Abstract

We study a class of objects called MDG algebras and MDG modules, which are just DG algebras and DG modules except we don't require the associative law to hold. Many interesting questions regarding DG algebras and DG modules can be studied in the broader class of MDG algebras and MDG modules. Using ideas from homological algebra as well as the theory of Gröbner bases, we develop tools which help us measure how far away MDG objects are from being DG objects. An interesting off-shoot that developed from this project is a Gröbner-based associativity test which works for any graded algebra over a field. This associativity test could potentially be used in an algorithm which is designed to detect associative multiplications on graded vector spaces.

Introduction

In this paper, we study algebraic structures which are similar to DG algebras, but without the requirement that they be associative. In particular, let $(R, \mathfrak{m}, \mathbb{k})$ be a local noetherian ring, let I be an ideal of R , and let $F = (F, d)$ be an R -free resolution of R/I with $F_0 = R$. The usual multiplication map $m: R/I \otimes_R R/I \rightarrow R/I$ can be lifted to a chain map $\mu: F \otimes_R F \rightarrow F$, denoted $a \otimes b \mapsto a \star_\mu b = ab$ where $a, b \in F$ (where we make the further simplification $a \star_\mu b = ab$ whenever μ is clear from context). Up to homotopy, μ is unital, strictly graded-commutative, and associative. It is clear that we can always choose μ to be unital on the nose (with $1 \in F$ being the identity element). It was shown in [BE77] that μ can even be chosen to be strictly graded-commutative on the nose as well. On the other hand, it may not be possible to choose μ such that it is associative on the nose. Indeed, in some cases it is known that it is impossible to choose μ such that it is associative on the nose (see [Avr81, Luk26] for more details on this). In any case, we will call μ a **multiplication on F** when it is unital and strictly graded-commutative (though not necessarily associative), and we will call $F = (F, d, \mu)$ an **MDG R -algebra**. The “M” stands for multiplication, the “D” stands for differential, and the “G” stands for grading; this explains our terminology. If μ also satisfies the associativity axiom, then we will also call F a **DG R -algebra**. Note that since $F_0 = R$, any chain map from $F \otimes_R F$ to F which is unital is already a lift of the usual multiplication on R/I .

Ever since [BE77], a lot of research has been dedicated to the question: “does there exist a DG R -algebra structure on F ”? In other words, can we find a multiplication μ on F which is associative? The reason this question is interesting is because we gain a lot of information about the “shape” of F when we know the answer to that question is “yes”. This question is especially interesting in the case when F is *minimal*, meaning $d(F) \subseteq \mathfrak{m}F$. Indeed, in this case, it was shown in [BE77] that if we also assume R is a domain and I is perfect, and we know that an associative multiplication on F exists, then one obtains important lower bounds of the betti numbers β_i of R/I . In particular, let $t = t_1, \dots, t_m$ be a maximal R -sequence contained in I and let $E = \mathcal{K}(t)$ be the Koszul R -algebra resolution of R/t . Any expression of the t_i in terms of the generators for I yields a canonical comparison map $E \rightarrow F$. Then it was shown in [BE77] that if F possesses the structure of a DG R -algebra, then the comparison map $E \rightarrow F$ is injective, whence we get the lower bound $\binom{m}{i} \leq \beta_i$ for each i . With this in mind, Buchsbaum and Eisenbud made the following conjecture:

Conjecture 1. *There exists an associative multiplication on F .*

As we mentioned above however, this conjecture turns out to be false. Avramov was the first to find a counterexample and had communicated this to Buchsbaum and Eisenbud. All was not lost however as Buchsbaum and Eisenbud noted in an updated version of [BE77] that the following weaker conjecture would still give still give substantially the same applications (such as the lower bound).

Conjecture 2. *There exists an associative E -scalar multiplication on F which gives F the structure of a DG E -module in such a way that the comparison map $E \rightarrow F$ may be taken to be a map of DG E -modules.*

Unfortunately, Avramov again showed in [Avr81] that even this need not be possible. The starting point for this paper is based on the observation that we can still obtain those lower bounds even in cases where it is known that F does not possess the structure of a DG R -algebra or even a DG E -module. Indeed, we just need to find a multiplication μ on F together with a comparison map $\varphi: E \rightarrow F$ such that $\varphi: E \rightarrow F$ is an **MDG R -algebra homomorphism**. In other words, μ doesn't need to be associative; we just need $\varphi: E \rightarrow F$ to be **multiplicative**, meaning $\varphi(ab) = \varphi(a)\varphi(b)$ for all $a, b \in E$. The proof given in [BE77] which shows $\varphi: E \rightarrow F$ is injective will still work in this case. To see that we really do gain something new from this perspective, we will over an example in Example (2.2) where it is known that we can't find a μ which is associative, nonetheless we can still find a non-associative μ together with a comparison map $\varphi: E \rightarrow F$ such that φ is multiplicative. Consequently, the lower bounds of the betti numbers continues to hold even in this case. Thus it makes sense to weaken Conjecture (2) even further:

Conjecture 3. *There exists a multiplication μ on F together with a comparison map $\varphi: E \rightarrow F$ such that φ is multiplicative.*

This paper consists of two parts: theory and applications. In the first part, we work over an arbitrary commutative ring R and develop the theory of MDG R -algebras A and MDG A -modules X . As we mentioned above, these are just DG algebras/modules except we don't require the associative law to hold. For this reason, it'll be important to introduce tools which will help us how far away an MDG A -module X is from being associative. In particular, we define the **associator** of X to be the chain map $[\cdot]: A \otimes A \otimes X \rightarrow X$ defined on elementary tensors by

$$[a_1 \otimes a_2 \otimes x] = (a_1 a_2)x - a_1(a_2 x) = [a_1, a_2, x]$$

for all $a_1, a_2 \in A$ and $x \in X$, where we denote by $[\cdot, \cdot, \cdot]: A \times A \times X \rightarrow X$ to be the unique map corresponding to $[\cdot]$ under via the universal mapping property of tensor products. We then consider the smallest MDG A -submodule of X which contains the image of the associator of X . We denote this by $\langle X \rangle$ and call it the **associator A -submodule** of X , and we study its homology. If $\langle X \rangle_i = 0$, then we say X is **associative** in degree i , and if $H_i \langle X \rangle = 0$, then we say X is **homologically associative**. Obviously associativity in degree i implies homological associativity in degree i , but it turns out the converse is true under certain conditions (minimal / local / bounded below / finitely generated). Thus under these conditions, homological associativity is a good substitute for associativity. We work out some of these concepts in a special case. In particular, we consider the case where $R = \mathbb{k}[x] = \mathbb{k}[x_1, \dots, x_d]$ where \mathbb{k} is a field and where $I = \langle \mathbf{m} \rangle = \langle m_1, \dots, m_r \rangle$ is a monomial ideal. In this case, the minimal R -free resolution F of R/\mathbf{m} has a very nice combinatorial description. For instance, if the conditions of such that the conditions in Theorem (1.2) hold, then F is supported on a simplicial complex, called the Scarf complex of R/\mathbf{m} (this construction was first described in [BPS98]). We then define the **multiplicator** of a chain map $\varphi: X \rightarrow Y$ between MDG A -modules. Just as the associator measures the failure of associativity, the multiplicator measures the failure of multiplicativity. Almost every concept/tool/construction that we discuss regarding the associator carries over to the multiplicator in the obvious way. The multiplicator and associator are intimately related to each other via identities like (22).

In the next section, we turn to applications for the theory we just developed. The first and main application of this paper is to describe a presentation of the maximal associative quotient $A/\langle A \rangle$ as a quotient of the symmetric DG R -algebra $B = S_R(A)$ modulo the B -ideal \mathfrak{b} generated by image of the multiplicator of the inclusion map $\iota: A \rightarrow B$. Here, A is an MDG R -algebra which is centered at R (meaning $A_0 = R$ and $A_i = 0$ for all $i < 0$). We denote the multiplication of A by \star , so as to not confuse it with the multiplicator \cdot of B . Then the multiplicator of the inclusion map $\iota: A \rightarrow B$ is defined on elementary tensors by $a_1 \otimes a_2$ by

$$[a_1 \otimes a_2] = a_1 \star a_2 - a_1 a_2 = [a_1, a_2].$$

Thus \mathfrak{b} is the DG B -ideal generated by the multiplicators $[a_1, a_2]$ for all $a_1, a_2 \in A$. We will show that

$$A/\langle A \rangle \simeq B/\mathfrak{b}$$

as DG R -algebras, where the isomorphism is natural in A and commutes with base change. In the case where A is acyclic, we obtain isomorphisms in homology

$$H_i \langle A \rangle \simeq H_{i+1}(A/\langle A \rangle) \simeq H_{i+1}(B/\mathfrak{b})$$

for all $i \geq 0$. In particular, under certain conditions (minimal / local / bounded below / finitely generated), we see that if A is associative in degree $i - 1$, then A is associative in degree i if and only if $H_{i+1}(B/\mathfrak{b}) = 0$. We then consider a special case where R is an integral domain with quotient field K and where $F = A$ is an MDG R -algebra centered at R whose underlying graded R -module is finite and free. We let e_1, \dots, e_n be an ordered homogeneous basis of F_+ as a graded R -module which is ordered in such a way that if $|e_j| > |e_i|$, then $j > i$. We denote by $R[e] = R[e_1, \dots, e_n]$ to be the free *non-strict* graded-commutative R -algebra generated by e_1, \dots, e_n (thus odd elements do not square to zero in $R[e]$). For each $1 \leq i, j \leq n$, we set $f_{i,j} = -[e_i, e_j]$; thus

$$f_{i,j} = e_i e_j - e_i \star e_j,$$

and we set $\mathcal{F} = \{f_{i,j}\}$. It is at this point that we pass to the quotient field K and study the ideal generated by \mathcal{F} in $K[e]$. We attach to $K[e]$ a special monomial order $>$ which makes it so that $\text{LM}(f_{i,j}) = e_i e_j$. Furthermore, when one calculates the S-polynomial of the pair $(f_{j,k}, f_{i,j})$ where $i \neq j$ and then divides this by \mathcal{F} , we obtain the associator $[e_i, e_j, e_k]!$ This makes sense in a more general setting where $F = (F, \star)$ is just a graded K -algebra (no differentials or complexes involved whatsoever). Thus one could potentially use this setup to calculate associators for arbitrary graded K -algebras and hence to develop a Gröbner-based associativity test. We end this section by studying multigraded MDG R -algebras. In particular, we assume $R = \mathbb{k}[x] = \mathbb{k}[x_1, \dots, x_d]$ is a multivariable polynomial ring over a field \mathbb{k} , I is a monomial ideal, and μ respects the multigrading on F . In this case, F obtains the structure of an \mathbb{N}^n -graded MDG R -algebra. For each i , we let m_i be the monomial corresponding to the multidegree of e_i , and we set $\tilde{e}_i = e_i/m_i$. Furthermore, we localize F at the multiplicatively

closed set $S = \{m_i\}$ and we set $\tilde{F} = F_{S,0}$ to be the multidegree $\mathbf{0}$ component of F_S . The \mathbb{N}^n -graded MDG R -algebra structure on F induces an MDG \mathbb{k} -algebra structure on \tilde{F} in the obvious way. We will show that F is a DG R -algebra if and only if \tilde{F} is a DG \mathbb{k} -algebra.

For our next application, we turn our attention towards the **associator functor** which takes an MDG A -module X to the MDG A -module $\langle X \rangle$ and takes an MDG A -module homomorphism $\varphi: X \rightarrow Y$ to the restriction map $\varphi: \langle X \rangle \rightarrow \langle Y \rangle$. The associator functor need not be exact. Indeed, let

$$0 \longrightarrow X \xrightarrow{\varphi} Y \xrightarrow{\psi} Z \longrightarrow 0 \quad (1)$$

be a short exact sequence of MDG A -modules. We obtain an induced sequence of MDG A -modules

$$0 \longrightarrow \langle X \rangle \xrightarrow{\varphi} \langle Y \rangle \xrightarrow{\psi} \langle Z \rangle \longrightarrow 0 \quad (2)$$

which is exact at $\langle X \rangle$ and $\langle Z \rangle$ but not necessarily exact at $\langle Y \rangle$. In order to ensure exactness of (2), we need to place a condition on (1); the condition being that Y is an **associative extension** of $\varphi(X)$, meaning $X \cap \langle Y \rangle = \langle \varphi(X) \rangle$. When this happens, we obtain a long exact sequence in homology:

$$\begin{array}{ccccccc} & & & \cdots & \longrightarrow & H_{i+1}\langle Z \rangle & \\ & & & & & \downarrow & \\ & & & & & H_i\langle X \rangle & \longrightarrow H_i\langle Y \rangle \longrightarrow H_i\langle Z \rangle \\ & & & & & \downarrow & \\ & & & & & H_{i-1}\langle X \rangle & \longrightarrow \cdots \end{array} \quad (3)$$

Thus has potential for applications. First it tells us that if Y is an associative extension of X , then Y is homologically associative if and only if X and Y/X are homologically associative. We end this with another potentially interesting application of this long exact sequence.

Acknowledgements

I want to express my sincere gratitude to my advisor Keri Wagstaff. It's hard to put into words how lucky I was to have her as an advisor. I am extremely thankful for all she has done for me. I also wish to thank Saeed Nasseh. He was my advisor at Georgia Southern University and had supervised my Masters Thesis (many of the ideas that I developed in this paper originated there). He was also the one who had recommended I study at Clemson under Keri Wagstaff. I am extremely thankful for this recommendation! I also want to thank John Baez for being such an inspiration to me (as well as many others). The first time I ever used LaTeX was when I converted his handwritten notes on Category Theory into LaTeX. This was actually a very huge deal for me because at the time because I had never actually written down Mathematics like that before. John was very helpful in getting me started here. Finally I want to thank my professors Josip Derado and Jonathan Lewin at Kennesaw State University, where I obtained by undergraduate degree. They were both extremely influential in my mathematical career, and I can't thank them enough for all they've done for me.

Part I

Theory

1 MDG Algebras and MDG Modules

We begin by defining MDG algebras. After defining MDG algebras, we then motivate their study by explaining how they arise naturally in the study of minimal free resolutions of cyclic modules.

1.1 MDG Algebras

Let R be a commutative ring and let $A = (A, d)$ be an R -complex:

$$A := \cdots \longrightarrow A_{n+1} \xrightarrow{d_{n+1}} A_n \xrightarrow{d_n} A_{n-1} \longrightarrow \cdots$$

Note that we can think of A as a graded R -module

$$A = \bigoplus_{i \in \mathbb{Z}} A_i$$

equipped with an R -linear map $d: A \rightarrow A$ which is graded of degree -1 and satisfies $d^2 = 0$. We further equip A with a chain map $\mu: A \otimes_R A \rightarrow A$. We denote by $\star_\mu: A \times A \rightarrow A$ (or more simply by \cdot if context is clear) to be the unique graded R -bilinear map which corresponds to μ via the universal mapping property of tensors products. Thus we have

$$\mu(a_1 \otimes a_2) = a_1 \star_\mu a_2 = a_1 a_2$$

for all $a_1, a_2 \in A$, where we make the further simplification in notation $a_1 \star_\mu a_2 = a_1 a_2$ when context is clear. Note that since μ is a chain map, \star_μ satisfies the **Leibniz law** which says

$$d(a_1 a_2) = d(a_1) a_2 + (-1)^{|a_1|} a_1 d(a_2)$$

for all $a_1, a_2 \in A$ with a_1 homogeneous, where $|a_1|$ denotes the homological degree of a_1 . Note also that the chain map μ induces a chain map $\bar{\mu}: H(A) \otimes_R H(A) \rightarrow H(A)$, given by

$$\bar{\mu}(\bar{a}_1 \otimes \bar{a}_2) = \overline{a_1 a_2} \quad (4)$$

for all $\bar{a}_1, \bar{a}_2 \in H(A)$ (where $a_1, a_2 \in A$ such that $d(a_1) = 0 = d(a_2)$ are representatives of \bar{a}_1 and \bar{a}_2) where the Leibniz law ensure (4) is well-defined. Here, we view $H(A)$ as a trivial R -complex whose underlying graded R -module is $H(A)$ and whose differential is the zero map. Thus $\bar{\mu}$ being a chain map is equivalent to it being just a graded R -linear map.

In order to simplify our notation in what follows, we often refer to the triple (A, d, μ) via its underlying graded R -module A , where we think of A as a graded R -module which is equipped with a differential $d: A \rightarrow A$, giving it the structure of an R -complex, and which is further equipped with a chain map $\mu: A \otimes_R A \rightarrow A$. For instance, if μ satisfies a property (such as being associative), then we also say A satisfies that property.

Definition 1.1. With the notation as above, we make the following definitions:

1. We say A is **unital** if there exists $1 \in A$ such that $1a = a = a1$ for all $a \in A$.
2. We say A is **graded-commutative** if $a_1 a_2 = (-1)^{|a_1||a_2|} a_2 a_1$ for all homogeneous $a_1, a_2 \in A$.
3. We say A is **strictly graded-commutative** if it is graded-commutative and satisfies the additional property that $a^2 = 0$ for all odd elements $a \in A$.
4. We say A is **associative** if $(a_1 a_2) a_3 = a_1 (a_2 a_3)$ for all $a_1, a_2, a_3 \in A$.

We say A is an **MDG R -algebra** if A is strictly graded-commutative, unital, and $H(A)$ is associative. Thus $H(A)$ obtains the structure of an associative, strictly graded-commutative R -algebra. We call μ the **multiplication** of A just as we call d the differential of A . We say A is **centered** at R if $A_0 = R$ and $A_i = 0$ for all $i < 0$. Suppose B is another MDG R -algebra and let $\varphi: A \rightarrow B$ be a function.

1. We say φ is **unital** if $\varphi(1) = 1$.
2. We say φ is **multiplicative** if $\varphi(a_1 a_2) = \varphi(a_1) \varphi(a_2)$ for all $a_1, a_2 \in A$.

We say $\varphi: A \rightarrow B$ is an **MDG R -algebra homomorphism** if it is a chain map which is both unital and multiplicative. We denote by \mathbf{A}_R to be the category of all MDG R -algebras and MDG R -algebra homomorphisms, and we denote by \mathbf{A}_R^c to be the fully faithful subcategory of \mathbf{A}_R whose objects are MDG R -algebras centered at R .

Remark 1. Let A be an MDG R -algebra. We view R itself as an MDG R -algebra itself where R has the trivial R -complex structure (where R sits in homological degree 0 and where the differential of R is the zero map). We have a canonical MDG R -algebra homomorphism $\iota: R \rightarrow A$ defined by $\iota(r) = r \cdot 1$ where we write \cdot to denote the R -scalar multiplication $R \times A \rightarrow A$.

1.2 MDG Algebra Resolutions of a Cyclic Module

Let I be an ideal of R , and let F be an R -free resolution of R/I such that $F_0 = R$. We denote by $\mathcal{C}(F \otimes_R F, F)$ to be the set of all chain maps from $F \otimes_R F$ to F (more generally, if X and Y are two R -complexes, then we denote by $\mathcal{C}(X, Y)$ to be the set of all chain maps from X to Y). A **multiplication on F** is a chain map $\mu \in \mathcal{C}(F \otimes_R F, F)$ which is unital (with $1 \in F$ being the identity element) and strictly graded-commutative (if we decide to equip F with a particular multiplication μ , giving it the structure of an MDG R -algebra, then we write $F = (F, d, \mu)$ and refer to μ as *the multiplication of F*). We denote by $\text{Mult}(F)$ to be the set of all multiplications on F .

We claim that every multiplication on F is automatically a lift of the usual multiplication m on R/I . Let us explain what this means: first note that F comes equipped with a canonical quasiisomorphism $\tau: F \rightarrow R/I$. Here we view R/I as a trivial R -complex which sits in homological degree 0. In homological degree 0, we have $\tau_0: R \rightarrow R/I$ where τ_0 is the canonical projection map. In homological degree i where $i \neq 0$, we have $\tau_i: F_i \rightarrow 0$ is the zero map. With this understood, we say μ is a **lift of m** if the following diagram of R -complexes commutes:

$$\begin{array}{ccc} F \otimes_R F & \xrightarrow{\mu} & F \\ \tau^{\otimes 2} \downarrow & & \downarrow \tau \\ R/I \otimes_R R/I & \xrightarrow{m} & R/I \end{array} \quad (5)$$

In homological degree $i \neq 0$, this diagram commutes for trivial reasons, so the only thing that we need to check is that the diagram commutes in homological degree 0. In homological degree 0, the diagram looks like:

$$\begin{array}{ccc} R \otimes_R R & \xrightarrow{\mu_0} & R \\ \tau_0^{\otimes 2} \downarrow & & \downarrow \tau_0 \\ R/I \otimes_R R/I & \xrightarrow{m} & R/I \end{array} \quad (6)$$

Note that μ_0 is R -linear, so it's completely determined by where it sends $1 \otimes 1$. The diagram (6) will commute if and only if μ_0 sends $1 \otimes 1$ to $1 + x$ for some $x \in I$. In fact, μ_0 is already forced to send $1 \otimes 1$ to 1 since μ is assumed to be unital with identity element 1. Thus if $r_1, r_2 \in R$, then

$$r_1 \star_{\mu} r_2 = (r_1 r_2)(1 \star_{\mu} 1) = r_1 r_2.$$

In other words, μ_0 agrees with the usual multiplication on R , and the diagram (6) automatically commutes in this case as well. Note that if S was an

Next, let J be an ideal contained in I and let G be an R -free resolution of R/J such that $G_0 = R$. Furthermore, we equip G with a multiplication ν giving it the structure of an MDG R -algebra resolution of R/J . Choose $\varphi: G \rightarrow F$ to be a lift of the map $R/J \rightarrow R/I$. We claim that if φ is multiplicative, then it is automatically unital. Indeed, suppose φ is multiplicative and write $\varphi(1) = r$ for some $r \in R$. Since φ is a lift of $R/J \rightarrow R/I$, we must have $r = 1 + x$ for some $x \in I$. Since R is local, this implies r is a unit. However multiplicativity of φ already implies $r^2 = r$, and thus we must have $r = 1$ since r is a unit. Thus under these assumptions, $\varphi: G \rightarrow F$ is an MDG algebra homomorphism if and only if it is multiplicative. Of particular interest is when J is generated by an R -sequence $\mathbf{t} = t_1, \dots, t_m$. In this case, we can choose G to be $\mathcal{K} = \mathcal{K}(\mathbf{t})$: the Koszul R -algebra resolution of R/\mathbf{t} .

We now want to show that $\text{Mult}(F)$ can be viewed as some sort of “convex” subset of $\mathcal{C}(F \otimes_R F, F)$. To see what this means, first recall that $\mathcal{C}(F \otimes_R F, F)$ has a natural R -module structure on it, but this R -module structure does not induce an R -module structure on $\text{Mult}(F)$ (if $r \in R \setminus \{1\}$ and $\mu \in \text{Mult}(F)$, then $r\mu$ will not be unital). The following lemma shows that it's better to interpret $\text{Mult}(F)$ as some sort of convex subset of $\mathcal{C}(F \otimes_R F, F)$:

Lemma 1.1. *Suppose $\mu, \nu \in \text{Mult}(F)$ and $\lambda \in \mathcal{C}(F, F)$. Then $\lambda\mu + (1 - \lambda)\nu \in \text{Mult}(F)$.*

Proof. Clearly $\lambda\mu + (1 - \lambda)\nu$ is a chain map. It is also unital since if $a \in F$, then we have

$$\begin{aligned} (\lambda\mu + (1 - \lambda)\nu)(1 \otimes a) &= \lambda\mu(1 \otimes a) + (1 - \lambda)\nu(1 \otimes a) \\ &= \lambda a + (1 - \lambda)a \\ &= a. \end{aligned}$$

A similar computation shows $(\lambda\mu + (1 - \lambda)\nu)(a \otimes 1) = a$. Finally, it is graded-commutative since if $a, b \in F$ are homogeneous, then we have

$$\begin{aligned} (\lambda\mu + (1 - \lambda)\nu)(a \otimes b) &= \lambda\mu(a \otimes b) + (1 - \lambda)\nu(a \otimes b) \\ &= (-1)^{|a||b|}\lambda\mu(b \otimes a) + (-1)^{|a||b|}(1 - \lambda)\nu(b \otimes a) \\ &= (-1)^{|a||b|}(\lambda\mu + (1 - \lambda)\nu)(b \otimes a). \end{aligned}$$

□

1.3 Motivating Example

Before we dive into the theory of MDG R -algebras, we provide some motivation for their study by discussing a combinatorial setting where they show up. The following construction was first described in [BPS98]: let $R = \mathbb{k}[x] = \mathbb{k}[x_1, \dots, x_d]$ where \mathbb{k} is a field and let $I = \langle \mathbf{m} \rangle = \langle m_1, \dots, m_r \rangle$ is a monomial ideal in R . For each subset $\sigma \subseteq \{1, \dots, r\}$, we denote $e_\sigma := \{e_i \mid i \in \sigma\}$ (thus $e_{123} = \{e_1, e_2, e_3\}$). We also set $m_\sigma := \text{lcm}(m_i \mid i \in \sigma)$ and we set $\alpha_\sigma \in \mathbb{Z}^n$ to be the exponent vector of m_σ . Let Δ be a finitely simplicial complex with r -vertices denoted e_1, \dots, e_r . The sequence of monomials \mathbf{m} induces a labeling of the faces of Δ as follows: we label the vertices e_1, \dots, e_r of Δ by the monomials m_1, \dots, m_r (so e_i is labeled by m_i). More generally, if e_σ a face of Δ , then we label it by m_σ . With the faces labeled this way, we call Δ an **\mathbf{m} -labeled simplicial complex** (or a labeled simplicial complex if \mathbf{m} is understood from context). Also, for each $\alpha \in \mathbb{Z}^n$, let Δ_α be the subcomplex of Δ defined by

$$\Delta_\alpha = \{\sigma \in \Delta \mid m_\sigma \text{ divides } x^\alpha\}.$$

We often denote the faces of Δ_α by $(x^\alpha / m_\sigma) e_\sigma$ instead of σ whenever context is clear.

Definition 1.2. We define an R -complex, denoted F_Δ (or more simply denoted F if Δ is understood from context) and called the **R -complex induced by Δ** as follows: the homogeneous component in homological degree $k \in \mathbb{Z}$ of the underlying graded R -module of F is given by

$$F_k := \begin{cases} \bigoplus_{\dim \sigma = k-1} R e_\sigma & \text{if } \sigma \in \Delta \text{ and } 0 \leq k \leq \dim \Delta + 1 \\ 0 & \text{else} \end{cases}$$

and the differential d is defined on the homogeneous generators of F by $d(e_\emptyset) = 0$ and

$$d(e_\sigma) = \sum_{i \in \sigma} (-1)^{\text{pos}(i, \sigma)} \frac{m_\sigma}{m_{\sigma \setminus i}} e_{\sigma \setminus i}$$

for all $\sigma \in \Delta \setminus \{\emptyset\}$ where $\text{pos}(i, \sigma)$, the **position of vertex i** in σ , is the number of elements preceding i in the ordering of σ , and $\sigma \setminus i$ denotes the face obtained from σ by removing i . In the case where Δ is the r -simplex, we call F the **Taylor complex**.

Observe that F also has the structure of a **multigraded \mathbb{k} -complex** (or an \mathbb{N}^n -graded \mathbb{k} -complex) since the differential d respects the multigrading. In other words, we have a decomposition of \mathbb{k} -complexes

$$F = \bigoplus_{\alpha \in \mathbb{N}^n} F_\alpha,$$

where the \mathbb{k} -complex F_α in multidegree $\alpha \in \mathbb{N}^n$ is defined as follows: the homogeneous component in homological degree $k \in \mathbb{Z}$ of the underlying graded \mathbb{k} -vector space is given by

$$F_{k, \alpha} := \begin{cases} \bigoplus_{\dim \sigma = k-1} \mathbb{k} \frac{x^\alpha}{m_\sigma} e_\sigma & \text{if } \sigma \in \Delta_\alpha \text{ and } 0 \leq k \leq \dim \Delta + 1 \\ 0 & \text{else} \end{cases}$$

and the differential d_α of F_α is just the restriction of d to F_α . Notice that the differential behaves exactly like boundary map of Δ_α does:

$$\begin{aligned} d_\alpha \left(\frac{x^\alpha}{m_\sigma} e_\sigma \right) &= \frac{x^\alpha}{m_\sigma} d(e_\sigma) \\ &= \frac{x^\alpha}{m_\sigma} \sum_{i \in \sigma} (-1)^{\text{pos}(i, \sigma)} \frac{m_\sigma}{m_{\sigma \setminus i}} e_{\sigma \setminus i} \\ &= \sum_{i \in \sigma} (-1)^{\text{pos}(i, \sigma)} \frac{x^\alpha m_\sigma}{m_\sigma m_{\sigma \setminus i}} e_{\sigma \setminus i} \\ &= \sum_{i \in \sigma} (-1)^{\text{pos}(i, \sigma)} \frac{x^\alpha}{m_{\sigma \setminus i}} e_{\sigma \setminus i}. \end{aligned}$$

Thus if we define $\varphi_\alpha: F_\alpha(1) \rightarrow \mathcal{S}(\Delta_\alpha)$ to be the unique graded \mathbb{k} -linear isomorphism such that $\frac{x^\alpha}{m_\sigma} e_\sigma \mapsto \sigma$, then from the computation above, we see that $d_\alpha \varphi_\alpha = \partial_\alpha d_\alpha$, and hence φ_α gives an isomorphism of \mathbb{k} -complexes

$\varphi: \Sigma^{-1}F_{\alpha} \simeq C(\Delta_{\alpha}; \mathbb{k})$, where $C(\Delta_{\alpha}, \mathbb{k})$ is the reduced chain complex of Δ_{α} over \mathbb{k} . In particular, this implies

$$\begin{aligned} H(F) &= \ker d / \operatorname{im} d \\ &= \left(\bigoplus_{\alpha \in \mathbb{Z}^n} \ker d_{\alpha} \right) / \left(\bigoplus_{\alpha \in \mathbb{Z}^n} \operatorname{im} d_{\alpha} \right) \\ &\cong \bigoplus_{\alpha \in \mathbb{Z}^n} (\ker d_{\alpha} / \operatorname{im} d_{\alpha}) \\ &= \bigoplus_{\alpha \in \mathbb{Z}^n} H(F_{\alpha}) \\ &\cong \bigoplus_{\alpha \in \mathbb{Z}^n} \tilde{H}(\Delta_{\alpha}, \mathbb{k})(-1). \end{aligned}$$

In other words, we have

$$H_i(F) \cong \bigoplus_{\alpha \in \mathbb{Z}^n} H_i(F_{\alpha}) \cong \bigoplus_{\alpha \in \mathbb{Z}^n} \tilde{H}_{i-1}(\Delta; \mathbb{k}).$$

for all $i \in \mathbb{Z}$. From this we easily get the following theorem:

Theorem 1.2. *F is an R -free resolution of R/\mathbf{m} if and only if for all $\alpha \in \mathbb{Z}^n$ either Δ_{α} is the void complex or Δ_{α} is acyclic. In particular, the Taylor complex is an R -free resolution of R/\mathbf{m} . Moreover, F is minimal if and only if $m_{\sigma} \neq m_{\sigma'}$ for every proper subface σ' of a face σ .*

We now assume that Δ satisfies the conditions in Theorem (1.2), so that F is the minimal free R -resolution of R/\mathbf{m} . One can show that it is always possible choose a multiplication on F which respects the multigrading. The following was shown to be a counterexample first discussed in [Luk26] shows that we cannot choose a multiplication which respects the multigrading and is associative:

Example 1.1. Let Δ be the simplicial complex whose vertex set is $\{e_1, e_2, e_3, e_4, e_5\}$ and whose faces consists of all subsets of $e_{1234} = \{e_1, e_2, e_3, e_4\}$ and $e_{345} = \{e_3, e_4, e_5\}$, pictured below:

Next suppose $R = \mathbb{k}[x, y, z, w]$ and let $\mathbf{m} = x^2, w^2, xy, zw, y^2z^2$. Then we obtain an \mathbf{m} -labeled simplicial complex $\Delta = (\Delta, \mathbf{m})$ which is pictured below:

Let F be the R -complex induced by Δ . Let's write down the homogeneous components of F as a graded module: we have

$$\begin{aligned} F_0 &= R \\ F_1 &= Re_1 + Re_2 + Re_3 + Re_4 + Re_5 \\ F_2 &= Re_{12} + Re_{13} + Re_{14} + Re_{23} + Re_{24} + Re_{34} + Re_{35} + Re_{45} \\ F_3 &= Re_{123} + Re_{124} + Re_{134} + Re_{234} + Re_{345} \\ F_4 &= Re_{1234} \end{aligned}$$

The differential $d: F \rightarrow F$ behaves just like the usual boundary map except some monomials can show up as coefficients. For instance,

$$d(e_{1234}) = -ye_{123} + ze_{124} - we_{134} + xe_{234}$$

Next let $\alpha = (1, 2, 2, 1)$. As a \mathbb{k} -vector space, F_α looks like:

$$F_\alpha = \mathbb{k} + \mathbb{k}xy^2ze_3 + \mathbb{k}yz^2we_4 + \mathbb{k}xwe_5 + \mathbb{k}yze_{34} + \mathbb{k}xe_{35} + \mathbb{k}we_{45} + \mathbb{k}e_{345}.$$

However F_α is more than just a \mathbb{k} -vector space: it has the structure of a \mathbb{k} -complex. Let's write down the homogeneous components of F_α as a graded \mathbb{k} -vector space

$$F_{0,\alpha} = \mathbb{k}$$

$$F_{1,\alpha} = \mathbb{k}xy^2ze_3 + \mathbb{k}yz^2we_4 + \mathbb{k}xwe_5$$

$$F_{2,\alpha} = \mathbb{k}yze_{34} + \mathbb{k}xe_{35} + \mathbb{k}we_{45}$$

$$F_{3,\alpha} = \mathbb{k}e_{345}$$

we think of this complex as corresponding to Δ_a pictured below

Now, choose a multiplication μ on F which gives it the structure of a \mathbb{N}^n -graded MDG algebra resolution of R/\mathfrak{m} over R . Since μ respects the multigrading and satisfies Leibniz law, we are forced to have

$$e_1e_5 = yz^2e_{14} + xe_{45}$$

$$e_1e_2 = e_{12}$$

$$e_2e_5 = y^2ze_{23} + we_{35}$$

$$e_2e_{45} = -yze_{234} + we_{345}$$

$$e_1e_{35} = yze_{134} - xe_{345}$$

$$e_1e_{23} = e_{123}$$

$$e_2e_{14} = -e_{124}$$

At this point however, one can conclude that F is not associative since

$$[e_1, e_5, e_2] = (e_1e_5)e_2 - e_1(e_5e_2) = -yzd(e_{1234}) \neq 0. \quad (7)$$

One can work (7) out by hand, however one of the main results of this paper is a method for calculating associators like (7) using tools from the theory of Gröbner bases. For instance, we used the following Singular code below to calculate the associator $[e_1, e_5, e_2]$:

```

LIB "ncalg.lib";

intvec v= 1:3, 2:5, 3:5;
ring A=(0,x,y,z,w),(e1,e2,e5,e12,e14,e23,e35,e45,e123,e124,e134,e234,e345),Wp(v);

matrix C[13][13]; matrix D[13][13]; int i; int j;
for (i=1; i<=13; i++) {for (j=1; j<=13; j++) {C[i,j]=(-1)^(v[i]*v[j]);}}
ncalgebra(C,D);

poly f(1)(5) = e1*e5-yz2*e14-x*e45;
poly f(1)(2) = e1*e2-e12;
poly f(2)(5) = e2*e5-y2z*e23-w*e35;
poly f(2)(45) = e2*e45+yz*e234-w*e345;
poly f(1)(35) = e1*e35-yz*e134+x*e345;
poly f(1)(23) = e1*e23-e123;
poly f(2)(14) = e2*e14+e124;
poly S(1)(5)(2) = f(1)(5)*e2+e1*f(2)(5);

ideal I = f(2)(14), f(2)(45), f(1)(23), f(1)(35), f(2)(5), f(1)(5);
reduce(S(1)(5)(2),b);

// [e1,e5,e2] = (y^2*z)*e123+(-x*y*z^2)*e124+(y*z*w)*e134+(-x*y*z)*e234
(-y^2*z)*e123+(y*z^2)*e124+(-y*z*w)*e134+(x*y*z)*e234

```

1.4 MDG Modules

We now want to define MDG A -modules where A is an MDG R -algebra.

Definition 1.3. Let X be an R -complex equipped with chain maps $\mu_{A,X}: A \otimes_R X \rightarrow X$ and $\mu_{X,A}: X \otimes_R A \rightarrow X$, denoted $a \otimes x \mapsto ax$ and $x \otimes a \mapsto xa$ respectively.

1. We say X is **unital** if $1x = x = x1$ for all $x \in X$.
2. We say X is **graded-commutative** if $ax = (-1)^{|a||x|}xa$ for all $a \in A$ homogeneous and $x \in X$ homogeneous. In this case, $\mu_{X,A}$ is completely determined by $\mu_{A,X}$, and thus we completely forget about it and write $\mu_X = \mu_{A,X}$.
3. We say X is **associative** if $a_1(a_2x) = (a_1a_2)x$ for all $a_1, a_2 \in A$ and $x \in X$.

We say X is an **MDG A -module** if it is graded-commutative, unital, and the graded R -linear map

$$\bar{\mu}_X: H(A) \otimes_R H(X) \rightarrow H(X)$$

induced by μ_X gives $H(X)$ the structure of an associative graded-commutative $H(A)$ -module. We call μ_X the **A -scalar multiplication** of X . If X is also associative, then we say X is a **DG A -module**. A map $\varphi: X \rightarrow Y$ between MDG A -modules X and Y is called an **MDG A -module homomorphism** if it is a chain map which is also **multiplicative**, meaning $\varphi(ax) = a\varphi(x)$ for all $a \in A$ and $x \in X$. We obtain a category, denoted \mathbf{M}_A , whose objects are MDG A -modules and whose morphisms are MDG A -module homomorphisms.

Example 1.2. Let A and B be MDG R -algebras and let $\varphi: A \rightarrow B$ be a chain map such that $\varphi(1) = 1$. Then we give B the structure of an MDG A -module by defining an A -scalar multiplication on B via

$$a \cdot b = \varphi(a)b$$

for all $a \in A$ and $b \in B$. Note that we need $\varphi(1) = 1$ in order for B to be unital as an MDG A -module. Also note that φ is an MDG A -module homomorphism if and only if it is an algebra homomorphism. Indeed, it is an A -module homomorphism if and only if for all $a_1, a_2 \in A$ we have

$$\varphi(a_1a_2) = a_1 \cdot \varphi(a_2) = \varphi(a_1)\varphi(a_2),$$

which is equivalent to saying φ is an algebra homomorphism (since we already have $\varphi(1) = 1$).

1.5 The Category of All MDG A -Modules

Let A be an MDG R -algebra. The category of all MDG A -modules forms an abelian category which is enriched over the category of all R -modules. Indeed, if X and Y are MDG A -modules, then the set of all MDG A -module homomorphisms from X to Y , denoted $\text{Hom}_A(X, Y)$, has the structure of an R -module, and moreover, the usual composition operation

$$\circ: \text{Hom}_A(Y, Z) \times \text{Hom}_A(X, Y) \rightarrow \text{Hom}_A(X, Z),$$

denoted $(g, f) \mapsto g \circ f = fg$, is R -bilinear. We also have a zero object, binary biproducts, as well as kernels and cokernels. For instance, if $\varphi: X \rightarrow Y$ is an MDG A -module homomorphism, then the kernel of φ , denoted $\ker \varphi$, is defined in the usual way as

$$\ker \varphi = \{x \in X \mid \varphi(x) = 0\}$$

together with the canonical inclusion map $\iota: \ker \varphi \rightarrow X$. The differential and A -scalar multiplication of $\ker \varphi$ are simply the ones obtained from X via restriction to $\ker \varphi$. Similarly the cokernel of φ is defined in the usual way as well. Thus the category of all MDG A -modules shares many of the same properties as the category of all DG B -modules where B is a DG R -algebra. Thus, the language we use in the category of MDG A -modules is often similar to the language used in the category of all DG B -modules. For instance, if X and Y are two MDG A -modules such that $X \subseteq Y$, then we say X is an **MDG A -submodule** of Y if the inclusion map $\iota: X \rightarrow Y$ is an MDG A -module homomorphism. In particular, this means that both the differential and A -scalar multiplication of Y restricts to a differential and A -scalar multiplication on X . Similarly, the MDG A -submodules \mathfrak{a} of A are often called **MDG ideals** of A or **MDG A -ideals**. An MDG A -ideal \mathfrak{p} is called a **prime ideal** if it satisfies the following property: if $a_1, a_2 \in A$ such that $a_1 a_2 \in \mathfrak{p}$ and $a_2 \notin \mathfrak{p}$, then $a_1 \in \mathfrak{p}$.

Having said all of this, there are some notable differences between the category of all DG B -modules and the category of all MDG A -modules. In particular, one must be careful when defining localization, tensor, and hom in the latter. In particular, if X and Y are MDG A -modules, then one can define the tensor complex $X \otimes_A Y$ as well as the hom complex $\text{Hom}_A^*(X, Y)$ in the usual way. Then tensor complex $X \otimes_A Y$ turns out to be an MDG A -module with the obvious A -scalar multiplication, however it need not be true that $A \otimes_A X \simeq X$. On the other hand, it may not be possible to give the hom complex $\text{Hom}_A^*(X, Y)$ the structure of an MDG A -module by defining A -scalar multiplication in the obvious way. Finally, if $S \subseteq A$ is a multiplicatively closed set, then one can make sense of the localization X_S , but only in the case where S satisfies some extra conditions. We include more details on this in the appendix.

2 Associators and Multiplicators

In order to get a better understanding as to how far away MDG objects are from being DG objects, we need to discuss associators and multiplicators. Associators will help us measure how far away an MDG A -module X is from being associative, whereas multiplicators will help up measure how far away a chain map $\varphi: X \rightarrow Y$ is from being multiplicative. Throughout this section, let A be an MDG R -algebra, let X be and Y be MDG A -modules, and let $\varphi: X \rightarrow Y$ be an MDG A -module homomorphism.

2.1 Associators

We begin by defining associators.

Definition 2.1. The **associator** of X is the chain map, denoted $[\cdot]_X$ (or more simply by $[\cdot]$ if X is understood from context), from $A \otimes_R A \otimes_R X$ to X defined by

$$[\cdot] := \mu(\mu \otimes 1 - 1 \otimes \mu).$$

Note that we use μ to denote both the multiplication μ_A on A and the A -scalar multiplication $\mu_{A, X}$ on X where context makes clear which multiplication μ refers to. We denote by $[\cdot, \cdot, \cdot]: A \times A \times X \rightarrow X$ to be the unique R -trilinear map which corresponds to $[\cdot]$ via the universal mapping property of tensor products. Thus we have

$$[a_1 \otimes a_2 \otimes x] = (a_1 a_2)x - a_1(a_2 x) = [a_1, a_2, x]$$

for all $a_1, a_2 \in A$ and $x \in X$.

2.1.1 Associator Identities

In order to familiarize ourselves with the associator we collect together some useful identities that the associator satisfies:

- For all $a_1, a_2 \in A$ homogeneous and $x \in X$ we have the Leibniz law

$$d[a_1, a_2, x] = [d(a_1), a_2, x] + (-1)^{|a_1|} [a_1, d(a_2), x] + (-1)^{|a_1|+|a_2|} [a_1, a_2, d(x)]. \quad (8)$$

- For all $a_1, a_2 \in A$ homogeneous and $x \in X$ homogeneous we have

$$[a_1, a_2, x] = -(-1)^{|a_1||a_2|+|a_1||x|+|a_2||x|} [x, a_2, a_1]. \quad (9)$$

- For all $a_1, a_2 \in A$ homogeneous and $x \in X$ homogeneous we have

$$[a_1, a_2, x] = -(-1)^{|a_1||x|+|a_2||x|} [x, a_1, a_2] - (-1)^{|a_1||a_2|+|a_1||x|} [a_2, x, a_1] \quad (10)$$

- For all $a_1, a_2 \in A$ homogeneous and $x \in X$ homogeneous we have

$$[a_1, a_2, x] = (-1)^{|a_1||a_2|} [a_2, a_1, x] + (-1)^{|a_2||x|} [a_1, x, a_2] \quad (11)$$

- For all $a_1, a_2, a_3 \in A$ and $x \in X$ we have

$$a_1[a_2, a_3, x] = [a_1 a_2, a_3, x] - [a_1, a_2 a_3, x] + [a_1, a_2, a_3 x] - [a_1, a_2, a_3] x \quad (12)$$

The way the signs in (9) show up can be interpreted as follows: in order to go from $[a_1, a_2, x]$ to $[x, a_2, a_1]$, we have to first swap a_1 with a_2 (this is where the $(-1)^{|a_1||a_2|}$ comes from), then swap a_1 with x (this is where the $(-1)^{|a_1||x|}$ comes from), and then finally swap a_2 with x (this is where the $(-1)^{|a_2||x|}$ comes from). We then obtain one extra minus sign by swapping terms in the associator at the final step:

$$\begin{aligned} [a_1, a_2, x] &= (a_1 a_2) x - a_1(a_2 x) \\ &= (-1)^{|a_1||a_2|} (a_2 a_1) x - (-1)^{|a_2||x|} a_1(x a_2) \\ &= (-1)^{|a_1||a_2|+|a_2||x|+|a_1||x|} x(a_2 a_1) - (-1)^{|a_2||x|+|a_1||x|+|a_1||a_2|} (x a_2) a_1 \\ &= (-1)^{|a_1||a_2|+|a_1||x|+|a_2||x|} (x(a_2 a_1) - (x a_2) a_1) \\ &= -(-1)^{|a_1||a_2|+|a_1||x|+|a_2||x|} [x, a_2, a_1]. \end{aligned}$$

A similar interpretation is also given to (10) and (11). For instance, in order to get from $[a_1, a_2, x]$ to $[x, a_1, a_2]$, we have to swap x with a_2 and then swap x with a_1 (this is where the $(-1)^{|a_1||x|+|a_2||x|}$ comes from). We do add an extra minus sign in (11) however since we never swap terms in the associator:

$$\begin{aligned} (-1)^{|a_1||a_2|} [a_2, a_1, x] + (-1)^{|a_2||x|} [a_1, x, a_2] &= (a_1 a_2) x - (-1)^{|a_1||a_2|} a_2(a_1 x) + (-1)^{|a_2||x|} (a_1 x) a_2 - a_1(a_2 x) \\ &= (a_1 a_2) x - (-1)^{|a_1||a_2|} a_2(a_1 x) + (-1)^{|a_1||a_2|} a_2(a_1 x) - a_1(a_2 x) \\ &= (a_1 a_2) x - a_1(a_2 x) \\ &= [a_1, a_2, x]. \end{aligned}$$

2.1.2 Alternative MDG Modules

If X is not associative, then one is often interested to know if X satisfies the following weaker property:

Definition 2.2. We say X is **alternative** if $[a, a, x] = 0$ for all $a \in A$ and $x \in X$.

In other words, X is alternative if for each $a \in A$ and $x \in X$, we have $a^2 x = a(ax)$. The reason behind the name “alternative” comes from the fact that in the case where $X = A$, then A is alternative if and only if the associator $[\cdot, \cdot, \cdot]$ is alternating:

Proposition 2.1. Let $a \in A$ and $x \in X$ be homogeneous.

1. We have $[a, a, x] = 0$ if and only if $[x, a, a] = 0$.
2. If $[a, a, x] = 0$, then $[a, x, a] = 0$. The converse holds if a is odd and $\text{char } R \neq 2$.
3. If a is even, we have $[a, x, a] = 0$, and if a is odd, we have $[a, x, a] = (-1)^{|x|} 2[a, a, x]$. In particular, if $\text{char } R = 2$, we always have $[a, x, a] = 0$.

Proof. From identities (9) and (11) we obtain

$$\begin{aligned} [a, a, x] &= -(-1)^{|a|}[x, a, a] \\ [a, x, a] &= (-1)^{|x||a|}(1 - (-1)^{|a|})[a, a, x]. \end{aligned}$$

In particular, we see that

$$[a, x, a] = \begin{cases} = (-1)^{|x|}2[a, a, x] = -(-1)^{|x|}2a(ax) & \text{if } a \text{ is odd} \\ 0 & \text{if } a \text{ is even} \end{cases} \quad (13)$$

Similarly we have

$$[a, a, x] = \begin{cases} (-1)^{|x|}\frac{1}{2}[a, x, a] & \text{if } a \text{ is odd and } \text{char } R \neq 2 \\ (-1)^{|a|}[x, a, a] & \text{if } a \text{ is even} \end{cases} \quad (14)$$

□

Remark 2. Suppose F is an MDG R -algebra whose underlying graded R -module is finite and free with e_1, \dots, e_n being a homogeneous basis. In order to show F is alternative, it is *not* enough to check $[e_i, e_i, e_j] = 0$ for all e_i, e_j in the homogeneous basis. Indeed, even in this case, observe that if e_i and e_j are odd, then

$$\begin{aligned} [e_i + e_j, e_i + e_j, e_k] &= [e_i, e_i, e_k] + [e_i, e_j, e_k] + [e_j, e_i, e_k] + [e_j, e_j, e_k] \\ &= [e_i, e_j, e_k] + [e_j, e_i, e_k] \\ &= [e_i, e_j, e_k] - [e_j, e_i, e_k] + (-1)^{|e_k|}[e_j, e_k, e_i] \\ &= (-1)^{|e_k|}[e_j, e_k, e_i]. \end{aligned}$$

Thus in order for F to be alternative, we certainly need $[a_1, a_2, a_3] = 0$ for all $a_1, a_2, a_3 \in F$ whenever both a_1 and a_3 are odd. For instance, consider the MDG R -algebra F given in Example (1.1). It is straightforward to check that $[e_\sigma, e_\sigma, e_\tau] = 0$ for all $\sigma, \tau \in \Delta$. However F is not alternative since $[e_1, e_5, e_2] \neq 0$.

2.1.3 The Maximal Associative Quotient

Let A be an MDG R -algebra and let X be an A -module. The **associator R -subcomplex** of X , denoted $[X]$, is the R -subcomplex of X given by the image of the associator of X . Thus the underlying graded R -module of $[X]$ is

$$[X] = \text{span}_R\{[a_1, a_2, x] \mid a_1, a_2 \in A \text{ and } x \in X\},$$

and the differential of $[X]$ is simply the restriction of the differential of X to $[X]$. The **associator A -submodule** of X , denoted $\langle X \rangle$, is defined to be the smallest A -submodule of X which contains $[X]$. The underlying graded R -module of $\langle X \rangle$ also has a simple description. Indeed, observe that

$$a_1(a_2[a_3, a_4, x]) = (a_1a_2)[a_3, a_4, x] - [a_1, a_2, [a_3, a_4, x]] \quad (15)$$

for all $a_1, a_2, a_3, a_4 \in A$ and $x \in X$. Using identities like (15) together with graded-commutativity, one can show that the underlying graded R -module of $\langle X \rangle$ is given by

$$\langle X \rangle = \text{span}_R\{a_1[a_2, a_3, x] \mid a_1, a_2, a_3 \in A \text{ and } x \in X\}$$

The quotient $X/\langle X \rangle$ is an associative A -module. We denote by $\rho: X \rightarrow X/\langle X \rangle$ to be the canonical quotient map and we call $X/\langle X \rangle$ (together with its canonical quotient map ρ) the **maximal associative quotient** of X . It satisfies the following universal mapping property: every MDG A -module homomorphism $\varphi: X \rightarrow Y$ in which Y is associative factors through a unique MDG A -module homomorphism $\bar{\varphi}: X/\langle X \rangle \rightarrow Y$, meaning $\bar{\varphi}\rho = \varphi$. We express this in terms of a commutative diagram as below:

$$\begin{array}{ccc} X & \xrightarrow{\rho} & X/\langle X \rangle \\ & \searrow \varphi & \downarrow \bar{\varphi} \\ & & Y \end{array} \quad (16)$$

Indeed, suppose $\varphi: X \rightarrow Y$ is any MDG A -module homomorphism where Y is associative. In particular, we must have $[X] \subseteq \ker \varphi$, and since $\langle X \rangle$ is the smallest MDG A -submodule of X which contains $[X]$, it follows that $\langle X \rangle \subseteq \ker \varphi$. Thus the map $\bar{\varphi}: X/\langle X \rangle \rightarrow Y$ given by $\bar{\varphi}(\bar{x}) := \varphi(x)$ where $\bar{x} \in X/\langle X \rangle$ is well-defined. Furthermore, it is easy to see that $\bar{\varphi}$ is an MDG A -module homomorphism and the unique such one which makes the diagram (16) commute.

2.1.4 Homological Associativity

Definition 2.3. Let A be an MDG R -algebra and let X be an A -module. The **associator homology** of X is the homology of the associator A -submodule of X . We often simplify notation and denote the associator homology of X by $H\langle X \rangle$ instead of $H(\langle X \rangle)$. We say X is **homologically associative** if $H\langle X \rangle = 0$ and we say X is homologically associative in degree i if $H_i\langle X \rangle = 0$. Similarly we say X is associative in degree i if $\langle X \rangle_i = 0$.

Clearly, if X is associative, then X is homologically associative. The converse holds under certain conditions.

Theorem 2.1. Assume that (R, \mathfrak{m}) is a local ring, that $\langle X \rangle$ is minimal (meaning $d\langle X \rangle \subseteq \mathfrak{m}\langle X \rangle$), and that each $\langle X \rangle_i$ is a finitely generated R -module. If X is associative in degree i , then X is associative in degree $i + 1$ if and only if X is homologically associative in degree $i + 1$. In particular, if $\langle X \rangle$ is also bounded below (meaning $\langle X \rangle_i = 0$ for $i \ll 0$), then X is associative if and only if X is homologically associative.

Proof. Clearly if X is associative in degree $i + 1$, then it is homologically associative in degree $i + 1$. To show the converse, assume for a contradiction that X is homologically associative in degree $i + 1$ but that it is not associative in degree $i + 1$. In other words, assume

$$H_{i+1}\langle X \rangle = 0 \quad \text{and} \quad \langle X \rangle_{i+1} \neq 0.$$

By Nakayama's Lemma, we can find homogeneous $a_1, a_2, a_3 \in A$ and homogeneous $x \in X$ such that $|a_1| + |a_2| + |a_3| + |x| = i + 1$ and such that $a_1[a_2, a_3, x] \notin \mathfrak{m}\langle X \rangle_{i+1}$. Since $\langle X \rangle_i = 0$ by assumption, we have $d(a_1[a_2, a_3, x]) = 0$. Also, since $\langle X \rangle$ is minimal, we have $d\langle X \rangle \subseteq \mathfrak{m}\langle X \rangle$. Thus $a_1[a_2, a_3, x]$ represents a nontrivial element in homology in degree $i + 1$. This is a contradiction. \square

The proof of Theorem (2.1) tells us something a bit more than what was stated in the proposition. To see this, we first need a definition:

Definition 2.4. Let X be an MDG A -module.

1. Assume that $\langle X \rangle$ is bounded below. The **lower associative index** of X , denoted $\text{la}\langle X \rangle$, is defined to be the smallest $i \in \mathbb{Z} \cup \{\infty\}$ such that $\langle X \rangle_i \neq 0$ where we set $\text{la}\langle X \rangle = \infty$ if X is associative. We extend this definition to case where $\langle X \rangle$ is not bounded below by setting $\text{la}\langle X \rangle = -\infty$.
2. Assume that $H\langle X \rangle$ is bounded below. The **lower homological associative index** of X , denoted $\text{lha}\langle X \rangle$, is defined to be the smallest $i \in \mathbb{Z} \cup \{\infty\}$ such that $H_i\langle X \rangle \neq 0$ where we set $\text{lha}\langle X \rangle = \infty$ if X is homologically associative. We extend this definition to case where $H\langle X \rangle$ is not bounded below by setting $\text{lha}\langle X \rangle = -\infty$.
3. Assume that $\langle X \rangle$ is bounded above. The **upper associative index** of X , denoted $\text{ua}\langle X \rangle$, is defined to be the largest $i \in \mathbb{Z} \cup \{\infty\}$ such that $\langle X \rangle_i \neq 0$ where we set $\text{ua}\langle X \rangle = -\infty$ if X is associative. We extend this definition to case where $\langle X \rangle$ is not bounded above by setting $\text{ua}\langle X \rangle = \infty$.
4. Assume that $H\langle X \rangle$ is bounded above. The **upper homological associative index** of X , denoted $\text{uha}\langle X \rangle$, is defined to be the largest $i \in \mathbb{Z} \cup \{\infty\}$ such that $H_i\langle X \rangle \neq 0$ where we set $\text{uha}\langle X \rangle = -\infty$ if X is homologically associative. We extend this definition to case where $H\langle X \rangle$ is not bounded above by setting $\text{uha}\langle X \rangle = \infty$.

With the lower associative index of X and the lower homological associative index of X defined, we see after analyzing the proof of Theorem (2.1), that if R is local, $\langle X \rangle$ is minimal and bounded below, and each $\langle X \rangle_i$ is finitely generated as an R -module, then we have $\text{la}\langle X \rangle = \text{lha}\langle X \rangle$. On the other hand, even if these conditions are satisfied, we often have $\text{ua}\langle X \rangle > \text{uha}\langle X \rangle$. For instance, we will see in Example (2.1) that $\text{ua}\langle F \rangle = 4$ and $\text{uha}\langle F \rangle = 3$. In the case that we're mostly interested in, R is a local noetherian ring and F is the minimal free R -resolution of R/I . In this case, we are interested in the quantity:

$$a(R/I) := \inf_{\mu \in \text{Mult}(F)} \{\text{uha}\langle F_\mu \rangle - \text{lha}\langle F_\mu \rangle + 1\},$$

where F_μ denotes F equipped with the multiplication μ . We call $a(R/I)$ the **associative index** of R/I . One can think of $a(R/I)$ as measuring the failure to put a DG algebra structure on F . In particular, there exists a DG algebra structure on F if and only if $a(R/I) = 0$. In Example (2.1), we have $a(R/I) = 1$. Thus there is no DG algebra structure on F in this case, but the fact that $a(R/I) = 1$ tells us that we can get extremely close.

Proof. Let $t \in I$. Thus $t = d(a)$ where $|a| = 1$. Let $m_a: X \rightarrow X$ be the multiplication by a map given by $m_a(x) = ax$ (in particular, m_a is R -linear). In particular, m_a restricts to an R -linear map $m_a: \langle X \rangle \rightarrow \langle X \rangle$. Observe that if $x \in X$, then

$$\begin{aligned} (dm_a + m_ad)(x) &= d(ax) + ad(x) \\ &= d(a)x - ad(x) + ad(x) \\ &= tx \\ &= m_t(x). \end{aligned}$$

In particular, we see that m_a is a homotopy from m_t to the zero map, which restricts to a homotopy $m_a: \langle X \rangle \rightarrow \langle X \rangle$ from $m_t: \langle X \rangle \rightarrow \langle X \rangle$ to the zero map. It follows that t annihilates both $H(X)$ and $H\langle X \rangle$. \square

We now assume that R is an integral domain with quotient field K . Furthermore we assume that the underlying graded R -module structure of both A and X is free. In this case, we set

$$A_K = \{a/r \mid a \in A \text{ and } r \in R \setminus \{0\}\} \quad \text{and} \quad X_K = \{x/r \mid x \in X \text{ and } r \in R \setminus \{0\}\}.$$

Note that A_K is an MDG K -algebra centered at K . Next we consider the conductor:

$$\mathfrak{c} = \{c \in A_K \mid c\langle X \rangle \subseteq \langle X \rangle\}.$$

The Leibniz law implies \mathfrak{c} is an R -complex. We set $Q = d(\mathfrak{c}_1) \cap R$. Then by the same argument as in the proposition above, we see that Q annihilates both $H(X)$ and $H\langle X \rangle$.

Example 2.1. Let us revisit Example (1.1) where $R = \mathbb{k}[x, y, z, w]$, $\mathbf{m} = x^2, w^2, zw, xy, y^2z^2$, and where F is the R -complex included by the labeled simplicial complex pictured below:

Choose a multiplication μ on F which respects the multigrading. Recall that since μ respects the multigrading and satisfies Leibniz law, we are forced to have

$$\begin{aligned} e_1e_5 &= yz^2e_{14} + xe_{45} \\ e_1e_2 &= e_{12} \\ e_2e_5 &= y^2ze_{23} + we_{35} \\ e_2e_{45} &= -yze_{234} + we_{345} \\ e_1e_{35} &= yze_{134} - xe_{345} \\ e_2e_{14} &= -xe_{124} \end{aligned}$$

Furthermore, we know that F is not associative since $[e_1, e_5, e_2] \neq 0$, however one can check that F is alternative. We want to calculate the associator homology of F . Observe that

$$\begin{aligned} \frac{e_1}{x}[e_1, e_5, e_2] &= \frac{1}{x} \left([e_1^2, e_5, e_2] - [e_1, e_1e_5, e_2] + [e_1, e_1, e_5e_2] - [e_1, e_1, e_5]e_2 \right) \\ &= -\frac{1}{x}[e_1, e_1e_5, e_2] \\ &= -\frac{1}{x}[e_1, yz^2e_{14} + xe_{45}, e_2] \\ &= -\frac{yz^2}{x}[e_1, e_{14}, e_2] - [e_1, e_{45}, e_2] \\ &= -[e_1, e_{45}, e_2]. \end{aligned}$$

It follows that $d(e_1/x) = x$ annihilates $H\langle F \rangle$. Similar calculations like this shows that $\mathbf{m} = \langle x, y, z, w \rangle$ annihilates $H\langle F \rangle$. It follows that

$$H_i\langle F \rangle \simeq \begin{cases} \mathbb{k} & \text{if } i = 3 \\ 0 & \text{else} \end{cases}$$

One can interpret this as saying that the multiplication μ is very close to being associative. Homologically speaking, the failure for μ to being associative is reflected in the fact that $\ell(H\langle F \rangle) = 1$. Note however that μ is not associative in homological degree 4 since

$$[e_1, e_{45}, e_2] = xyz e_{1234} \neq 0.$$

In particular we have $\text{uha}(F) = \text{lha}(F) = 3$, but $\text{ua}(F) = 4$. In some sense however, the nonzero associator $[e_1, e_{45}, e_2]$ isn't really anything *new*. Indeed, we obtained the nonzero associator $[e_1, e_{45}, e_2]$ from the nonzero associator $[e_1, e_5, e_2]$, so one could argue that $[e_1, e_{45}, e_2]$ being nonzero is simply a direct consequence of $[e_1, e_5, e_2]$ being nonzero. More generally, a nonzero associator $\chi \in \langle F \rangle$ should only be thought of as contributing something new towards the failure for μ to being associative if $d(\chi) = 0$ (otherwise one could argue that χ being nonzero is simply a direct consequence of the associators in $d(\chi)$ being nonzero). Similarly, if $\chi = d(\chi')$ for some other nonzero associator $\chi' \in \langle F \rangle$, then again χ isn't contributing anything new towards the failure for μ to being associative, since one could argue that χ being nonzero is a direct consequence of χ' being nonzero. Thus the associators which really do contribute something new towards the failure for μ being associative should be the ones which represent nonzero elements in homology. In this case, we have precisely one nontrivial nonzero associator $[e_1, e_5, e_2]$ which represents a nontrivial element in homology (all other nonzero associators can be derived from the fact that $[e_1, e_5, e_2] \neq 0$).

2.2 Multiplicators

Having discussed associators, we now wish to discuss multiplicators.

Definition 2.5. Let X and Y be MDG A -modules and let $\varphi: X \rightarrow Y$ be a chain map.

1. The **multiplicator** of φ is the chain map, denoted $[\cdot]_\varphi$, from $A \otimes_R X$ to Y defined by

$$[\cdot]_\varphi := \varphi\mu - \mu(1 \otimes \varphi).$$

Note that we use μ to denote both A -multiplications $\mu_{A,X}$ and $\mu_{A,Y}$ where context makes clear which multiplication μ refers to. We denote by $[\cdot, \cdot]_\varphi: A \times X \rightarrow Y$ (or more simply by $[\cdot, \cdot]$ if context is clear) to be the unique graded R -bilinear map which corresponds to $[\cdot]_\varphi$. Thus we have

$$[a \otimes x]_\varphi = \varphi(ax) - a\varphi(x) = [a, x]$$

for all $a \in A$ and $x \in X$. We say φ is **multiplicative** if $[\cdot]_\varphi = 0$.

2. The **2-multiplicator** of φ is the chain map, denoted $[\cdot]_\varphi^{(2)}$, from $A \otimes_R A \otimes_R X$ to Y defined by

$$[\cdot]_\varphi^{(2)} := \varphi[\cdot]_\mu - [\cdot]_\mu(1 \otimes 1 \otimes \varphi)$$

where we write $[\cdot]_\mu$ to denote both the associator of X and the associator Y where context makes clear which multiplication μ refers to. We denote by $[\cdot, \cdot, \cdot]_\varphi: A \times X \rightarrow Y$ to be the unique graded R -bilinear map which corresponds to $[\cdot]_\varphi^{(2)}$ (in order to avoid confusion with the associator, we will *always* keep φ in the subscript of $[\cdot, \cdot, \cdot]_\varphi$). Thus we have

$$[a_1 \otimes a_2 \otimes x]_\varphi^{(2)} = \varphi([a_1, a_2, x]) - [a_1, a_2, \varphi(x)] = [a_1, a_2, x]_\varphi$$

for all $a_1, a_2 \in A$ and $x \in X$. We say φ is **2-multiplicative** if $[\cdot]_\varphi^{(2)} = 0$.

Remark 4. If A and B are MDG R -algebras and $\varphi: A \rightarrow B$ is a chain map such that $\varphi(1) = 1$, then we view B as an MDG A -module with the A -scalar multiplication defined by $a \cdot b = \varphi(a)b$. In this case, the multiplicator of φ has the form

$$[a_1, a_2]_\varphi = \varphi(a_1 a_2) - \varphi(a_1)\varphi(a_2)$$

for all $a_1, a_2 \in A$.

Example 2.2. Let us continue with Example (1.1). Let $\mathbf{m}' = x^2, w^2, y^2 z^2$ and let $E = \mathcal{K}(\mathbf{m}')$ be the Koszul R -algebra which resolves R/\mathbf{m}' . The homogeneous basis of E' is denoted by e'_σ . Choose a comparison map $\varphi': E' \rightarrow F$ which lifts the projection $R/\mathbf{m}' \rightarrow R/\mathbf{m}$ such that φ' is unital and respects the multigrading. Then φ' being a

chain map together with the fact that it is unital and respects the multigrading forces us to have

$$\begin{aligned}\varphi'(e'_1) &= e_1 \\ \varphi'(e'_2) &= e_2 \\ \varphi'(e'_3) &= e_5 \\ \varphi'(e'_{12}) &= e_{12} \\ \varphi'(e'_{13}) &= yz^2e_{14} + xe_{45} \\ \varphi'(e'_{23}) &= y^2ze_{23} + we_{35}.\end{aligned}$$

Suppose that we also have

$$\varphi'(e'_{123}) = yz^2e_{124} + xzye_{234} - xwe_{345}.$$

We can picture $\varphi'(E')$ inside of F as being supported on the red-shaded subcomplex below:

We now ask: is φ' an MDG algebra homomorphism? The answer is no. Indeed, clearly this map is a chain map which fixes the identity element, however it is not multiplicative. In fact, it's not even 2-multiplicative. To see this, assume for a contradiction that it was 2-multiplicative. Then we'd have

$$\begin{aligned}0 &= \varphi'(0) \\ &= \varphi'([e'_1, e'_2, e'_3]) \\ &= [\varphi'(e'_1), \varphi'(e'_2), \varphi'(e'_3)] \\ &= [e_1, e_2, e_5] \\ &\neq 0,\end{aligned}$$

which is an obvious contradiction.

Next let $\mathbf{m}'' = x^2, w^2, zw, xy$ and let $T'' = \mathcal{T}(\mathbf{m}'')$ be the Taylor algebra which resolves R/\mathbf{m}'' . The homogeneous basis of T'' is denoted by e''_σ . Choose a comparison map $\varphi'': T'' \rightarrow F$ which lifts the projection $R/\mathbf{m}' \rightarrow R/\mathbf{m}$ such that φ'' is unital and respects the multigrading. Then φ'' being a chain map together with the fact that it is multigraded forces us to have $\varphi''(e''_\sigma) = e_\sigma$ for all σ . We can picture $\varphi''(T'')$ inside of F as being supported on the red-shaded subcomplex below:

This time it is easy to check that φ'' is an MDG algebra homomorphism. We give F the structure of an MDG T'' -module using φ'' in the usual way. Notice that F is *not* associative as a T'' -module, that is F is not a DG T'' -module. Indeed, we have $[e_1, e_2, e_5] \neq 0$.

Finally let $\mathbf{t} = x^2 + w^2, w^2 + zw, zw + xy, x^3 + w^3$. One can check that \mathbf{t} is an R -regular sequence contained in I . Thus the Koszul algebra $E = \mathcal{K}(\mathbf{t})$ resolves R/\mathbf{t} . The homogeneous basis of E is denoted by ε_σ . We begin to construct a comparison map $\varphi: E \rightarrow F$ such that

$$\begin{aligned}\varphi(\varepsilon_1) &= e_1 + e_2 \\ \varphi(\varepsilon_2) &= e_2 + e_3 \\ \varphi(\varepsilon_3) &= e_3 + e_4 \\ \varphi(\varepsilon_4) &= xe_1 + we_2.\end{aligned}$$

It is straightforward to check that this extends to a unique MDG algebra homomorphism by setting

$$\varphi(\varepsilon_\sigma) = \prod_{i \in \sigma} \varphi(\varepsilon_i).$$

We give F the structure of an MDG E -module using φ in the usual way. Again, note that F is not a DG E -module, however $\varphi: E \rightarrow F$ is an MDG algebra homomorphism.

2.2.1 Multiplier Identities

We want to familiarize ourselves with the multiplier of $\varphi: X \rightarrow Y$, so in this subsection we collect together some identities which the multiplier satisfies:

- For all $a \in A$ homogeneous and $x \in X$, we have the Leibniz law:

$$d[a, x] = [da, x] + (-1)^{|a|}[a, dx].$$

- For all $a \in A$ homogeneous and $x \in X$ homogeneous, we have

$$[a, x] = (-1)^{|a||x|}[x, a]. \quad (19)$$

- For all $a_1, a_2 \in A$ and $x \in X$, we have

$$a_1[a_2, x] - [a_1a_2, x] + [a_1, a_2x] = [a_1, a_2, x]_\varphi \quad (20)$$

Furthermore, if $\psi: Y \rightarrow Z$ is another chain map, then for all $a \in A$ and $x \in X$, we have

$$[a, x]_{\psi\varphi} = \psi([a, x]_\varphi) + [a, \varphi(x)]_\psi \quad (21)$$

In particular, if ψ is multiplicative, then $\psi([Y]_\varphi) \subseteq [Z]_{\psi\varphi}$.

Remark 5. Let A and B be MDG R -algebras and let $\varphi: A \rightarrow B$ be a chain map such that $\varphi(1) = 1$. Then we can rewrite (20) as follows: for all $a_1, a_2, a_3 \in A$, we have

$$\varphi(a_1)[a_2, a_3] - [a_1a_2, a_3] + [a_1, a_2a_3] - [a_1, a_2]\varphi(a_3) = [\varphi(a_1), \varphi(a_2), \varphi(a_3)] - \varphi([a_1, a_2, a_3]) \quad (22)$$

Indeed, this follows from the fact that

$$[\varphi(a_1), \varphi(a_2), \varphi(a_3)] = [a_1, a_2, \varphi(a_3)] - [a_1, a_2]\varphi(a_3).$$

We also have $[a, a]_\varphi = 0$ for all $a \in A$ odd.

§

2.2.2 The Maximal Multiplicative Quotient

Let $\varphi: X \rightarrow Y$ be a chain map between MDG A -modules X and Y . The **multiplier complex** of φ , denoted $[Y]_\varphi$, is the R -subcomplex of Y given by $[Y]_\varphi := \text{im } [\cdot]_\varphi$, so the underlying graded module of $[Y]_\varphi$

$$[Y]_\varphi := \text{span}_R\{[a, x]_\varphi \mid a \in A \text{ and } x \in X\},$$

and the differential of $[Y]_\varphi$ is simply the restriction of the differential of Y to $[Y]_\varphi$. In order to avoid confusion with the associator complex, we will always write φ in the subscript of $[Y]_\varphi$. Even though the multiplier complex of φ is closed under the differential, it need not be closed under A -scalar multiplication. In other words, if $a_1, a_2 \in A$ and $x \in X$, then it need not be the case that $a_1[a_2, x]_\varphi \in [Y]_\varphi$. We denote by $\langle Y \rangle_\varphi$ to be the MDG A -submodule of Y generated by $[Y]_\varphi$. In other words, $\langle Y \rangle_\varphi$ is the smallest MDG A -submodule of Y which contains $[Y]_\varphi$. Unlike the associator submodule, the multiplier submodule is difficult to describe in terms of an R -span of elements. Indeed, as a first guess, one might think that $\langle Y \rangle_\varphi$ is given by

$$\text{span}_R\{[a, x]_\varphi \mid a \in A \text{ and } x \in X\}. \quad (23)$$

However this is clearly incorrect in general as we may need to adjoin elements of the form $a_1[a_2, x]$ to (23). As a second guess, one might think that $\langle Y \rangle_\varphi$ is given by

$$\text{span}_R\{a_1[a_2, x]_\varphi \mid a_1, a_2 \in A \text{ and } x \in X\}. \quad (24)$$

However this isn't correct in general either since the identity

$$a_1(a_2[a_3, x]_\varphi) = (a_1a_2)[a_3, x]_\varphi - [a_1, a_2, [a_3, x]_\varphi]$$

tells us that should really adjoin elements of the form $a_1[a_2, a_3, [a_4, x]]$ to (24) as well. As a third guess, one might think that $\langle Y \rangle_\varphi$ is given by

$$\text{span}_R\{a_1[a_2, x]_\varphi, a_1[a_2, a_3, [a_4, x]_\varphi] \mid a_1, a_2, a_3, a_4 \in A \text{ and } x \in X\}. \quad (25)$$

Again this isn't correct in general since the identity

$$a_1(a_2[a_3, a_4, [a_5, x]_\varphi]) = (a_1 a_2)[a_3, a_4, [a_5, x]] - [a_1, a_2, [a_3, a_4, [a_5, x]_\varphi]].$$

tells us that we should really adjoin elements of the form $a_1[a_2, a_3, [a_4, a_5, [a_6, x]_\varphi]]$ to (25) as well. The problem continues getting worse with no end in sight. It turns out however, that if φ is 2-multiplicative, then $\langle Y \rangle_\varphi$ given by (23).

Proposition 2.3. *If φ is 2-multiplicative, then for all $a_1, a_2, a_3 \in A$ and $x \in X$ we have*

$$a_1[a_2, x]_\varphi = [a_1 a_2, x]_\varphi - [a_1, a_2 x]_\varphi \quad \text{and} \quad [a_1, a_2, [a_3, x]_\varphi] = [[a_1, a_2, a_3], x]_\varphi - [a_1, [a_2, a_3, x]]_\varphi. \quad (26)$$

In particular, $\langle Y \rangle_\varphi$ is given by (23).

Proof. A straightforward calculation yields

$$a_1[a_2, a_3, x]_\varphi = [a_1 a_2, a_3, x]_\varphi - [a_1, a_2 a_3, x]_\varphi + [a_1, a_2, a_3 x]_\varphi - [[a_1, a_2, a_3], x]_\varphi + [a_1, [a_2, a_3, x]]_\varphi - [a_1, a_2, [a_3, x]_\varphi].$$

Using this identity together with the identity (20), we see that if φ is 2-multiplicative, then we obtain (26). This implies all elements of the form $a_1[a_2, x]$ and $a_1[a_2, a_3, [a_4, x]]$ belong to (23). An easy induction argument shows that $\langle Y \rangle_\varphi$ is given by (23). \square

The quotient $Y/\langle Y \rangle_\varphi$ is an MDG A -module. We denote by $\pi: Y \rightarrow Y/\langle Y \rangle_\varphi$ to be the canonical quotient map. Note that both π and $\pi\varphi$ are multiplicative. Therefore (21) implies $[Y]_\varphi \subseteq \ker \pi$ which implies $\langle Y \rangle_\varphi \subseteq \ker \pi$. We call $Y/\langle Y \rangle_\varphi$ (together with its canonical quotient map π) the **maximal multiplicative quotient** of $\varphi: X \rightarrow Y$; it satisfies the following universal mapping property: for all chain maps $\psi: Y \rightarrow Z$ where both ψ and $\psi\varphi$ are MDG A -module homomorphisms (hence both are multiplicative), then there exists a unique MDG A -module homomorphism $\bar{\psi}: Y/\langle Y \rangle_\varphi \rightarrow Z$ such that $\bar{\psi}\pi = \psi$. We express this in terms of a commutative diagram as below:

$$\begin{array}{ccc} X & \xrightarrow{\varphi} & Y \\ & \searrow \psi & \downarrow \pi \\ Z & \xleftarrow{\bar{\psi}} & Y/\langle Y \rangle_\varphi \end{array} \quad (27)$$

Indeed, suppose $\psi: Y \rightarrow Z$ is such a map. Then (21) implies $[Y]_\varphi \subseteq \ker \psi$ which implies $\langle Y \rangle_\varphi \subseteq \ker \psi$. Thus the map $\bar{\psi}: Y/\langle Y \rangle_\varphi \rightarrow Z$ given by

$$\bar{\psi}(\bar{y}) := \psi(y),$$

where $\bar{y} \in Y/\langle Y \rangle_\varphi$ and where $y \in Y$ is a choice of an element in Y such that $\pi(y) = \bar{y}$, is well-defined. Furthermore, it is easy to check that $\bar{\psi}$ is an MDG A -module homomorphism and the unique such map which makes the diagram (29) commute.

3 The Symmetric DG Algebra

Let A be an R -complex centered at R (thus $A_0 = R$ and $A_i = 0$ for all $i < 0$). In this section, we will construct the symmetric DG algebra of A , which we denote by $S(A)$. Before we construct it rigorously, we describe it informally first in order to help motivate the reader. The underlying R -module of $S(A)$ has a bi-graded structure, more specifically, we can decompose $S(A)$ into R -modules as:

$$S(A) = \bigoplus_{i \geq 0} S_i(A) = \bigoplus_{m \geq 0} S^m(A) = \bigoplus_{i, m \geq 0} S_i^m(A)$$

We refer to the i in the subscript as **homological degree** and we refer to the m in the superscript as **total degree**. The R -module $S_i^m(A)$ can be described as follows: first we have

$$S_0(A) = S^0(A) = S_0^0(A) = R.$$

Next, for $i, m \geq 1$, the R -module $S_i^m(A)$ is the R -span of all elementary products of the form $a_1 \cdots a_m$ where $a_1, \dots, a_m \in A_+$ are homogeneous such that

$$|a_1| + \cdots + |a_m| = i.$$

We identify A with its image in $S(A)$ and let $\iota: A \rightarrow S(A)$ denote the inclusion map. Thus we have

$$A = S^0(A) + S^1(A) = R + A_+.$$

The differential of $S(A)$ extends the differential of A and is defined on elementary products of the form $a_1 \cdots a_m$ where $a_1, \dots, a_m \in A_+$ are homogeneous by

$$d(a_1 \cdots a_m) = \sum_{j=1}^m (-1)^{|a_1| + \cdots + |a_{j-1}|} a_1 \cdots d(a_j) \cdots a_m.$$

In the next example, we consider an R -free resolution F of a cyclic R -module and we work out what $S(F)$ looks like.

Example 3.1. Let $R = \mathbb{k}[x, y]$, let $I = \langle x^2, xy \rangle$, and let F be Taylor resolution of R/I . Let's write down the homogeneous components of F as a graded R -module: we have

$$\begin{aligned} F_0 &= R \\ F_1 &= Re_1 + Re_2 \\ F_2 &= Re_{12}, \end{aligned}$$

and if $i \notin \{0, 1, 2\}$, then $F_i = 0$. The differential of F is defined on the homogeneous basis elements by

$$\begin{aligned} d(e_1) &= x^2 \\ d(e_2) &= xy \\ d(e_{12}) &= xe_2 - ye_1. \end{aligned}$$

Note that the Taylor resolution usually comes equipped with a multiplication called the Taylor multiplication. Let us denote this by \star so as not to confuse it with the multiplication \cdot of $S(F)$. Now let's write down the homogeneous components of $S(F)$ as a graded R -module (with respect to homological degree): we have

$$\begin{aligned} S_0(F) &= R \\ S_1(F) &= Re_1 + Re_2 \\ S_2(F) &= Re_{12} + Re_1e_2 \\ S_3(F) &= Re_1e_{12} + Re_2e_{12} \\ S_4(F) &= Re_{12}^2 + Re_1e_2e_{12} \\ &\vdots \end{aligned}$$

Note that $S_4^3(F) = Re_1e_2e_{12}$ and $S_4^2(F) = Re_{12}^2$. Also note that

$$\begin{aligned} d(e_1e_2 - e_1 \star e_2) &= d(e_1e_2 - xe_{12}) \\ &= d(e_1)e_2 - e_1d(e_2) - xd(e_{12}) \\ &= x^2e_2 - xye_1 - x(xe_2 - ye_1) \\ &= x^2e_2 - xye_1 - x^2e_2 + xye_1 \\ &= 0. \end{aligned}$$

3.1 Construction of the Symmetric DG Algebra of A

We now provide a rigorous construction of $S(A)$. This will occur in three steps.

Non-Unital Tensor Algebra

We define the **non-unital tensor algebra** of A to be the associative, graded, and non-unital R -algebra

$$U(A) = \bigoplus_{i,k,m \geq 0} U_i^{k,m}(A).$$

The component $U_i^{k,m}(A)$ consists of all finite R -linear combinations of elementary tensors of the form

$$1^{\otimes k} \otimes a_1 \otimes \cdots \otimes a_m = 1 \otimes \cdots \otimes 1 \otimes a_1 \otimes \cdots \otimes a_m \quad (28)$$

where $a_1, \dots, a_m \in A_+$ are homogeneous such that

$$|a_1| + \dots + |a_m| = i$$

We think of (28) as being graded of total degree m by setting $\deg(1) = 0$ and $\deg(a) = 1$ for all $a \in A_+$ and extending this multiplicatively. The multiplication of $U(A)$ is defined on such elementary tensors by

$$(1^{\otimes k} \otimes a_1 \otimes \dots \otimes a_m) \otimes (1^{\otimes k'} \otimes a'_1 \otimes \dots \otimes a'_{m'}) \mapsto 1^{\otimes (k+k')} \otimes a_1 \otimes \dots \otimes a_m \otimes a'_1 \otimes \dots \otimes a'_{m'}$$

and is extended R -linearly everywhere else. In particular, note that $U(A)$ is not unital since $a \otimes 1 = 1 \otimes a \neq a$ for all nonzero $a \in A$. We set \mathfrak{t} to be the $U(A)$ -ideal generated by all elements of the form $1 \otimes a - a$ where $a \in A$.

Tensor Algebra

The **tensor algebra** of A , denoted $T(A)$, is defined to be the quotient

$$T(A) := U(A)/\mathfrak{t}.$$

The image of the elementary tensor (28) in $T(A)$ is denoted by $a_1 \otimes \dots \otimes a_m$. Since \mathfrak{t} is generated by elements of the form $1 \otimes a - a$, which are homogeneous with respect to the homological degree and total degree, we see that $T(A)$ is an associative and unital R -algebra which is bi-graded with respect to homological degree and total degree. In particular, we have $T_0(A) = R = T^0(A)$, and for $m \geq 1$, the component of $T(A)$ in total degree m is given by

$$T^m(A) = A_+^{\otimes m}$$

where the tensor product is taken over R . On the other hand, for $i \geq 1$, the component of $T(A)$ in homological degree i consists of the R -span of all homogeneous elementary tensors of the form $a_1 \otimes \dots \otimes a_m$ where $m \geq 1$ and where a_1, \dots, a_m are homogeneous elements in A_+ such that

$$|a_1| + \dots + |a_m| = i.$$

Define $\sigma: T^{\leq 2}(A) \rightarrow T(A)$ by setting $\sigma(a) = a$ for all $a \in A$ and $\sigma(a_1 \otimes a_2) = (-1)^{|a_1||a_2|} a_2 \otimes a_1$ for all $a_1, a_2 \in A_+$ and then extending it everywhere else R -linearly. Clearly σ is a chain map with $\sigma(1) = 1$. Note that the multiplier of σ has the form

$$[a_1, a_2]_\sigma = \sigma(a_1 \otimes a_2) - \sigma(a_1) \otimes \sigma(a_2) = (-1)^{|a_1||a_2|} a_2 \otimes a_1 - a_1 \otimes a_2$$

for all $a_1, a_2 \in A_+$. We set \mathfrak{s} to be the $T(A)$ -ideal generated by the multiplier complex of σ .

Symmetric Algebra

The **symmetric algebra** of A , denoted $S(A)$, is defined to be the quotient $S(A) := T(A)/\mathfrak{s}$. Since \mathfrak{s} is generated by elements which are homogeneous with respect to both homological degree and total degree, we see that $S(A)$ inherits from $T(A)$ the structure of a bi-graded associative R -algebra which is also strictly graded-commutative with respect to homological degree. The image of the elementary tensor $a_1 \otimes \dots \otimes a_m$ in $T(A)$ will be denoted by $a_1 \cdots a_m$ in $S(A)$ and we refer to $a_1 \cdots a_m$ as an elementary product. Thus we have $S^0(A) = S_0(A) = R$, and for $i, m \geq 1$ the component $S_i^m(A)$ consists of all finite R -linear combinations of elementary products of the form $a_1 \cdots a_m$ where a_1, \dots, a_m are homogeneous elements in A_+ such that

$$|a_1| + \dots + |a_m| = i.$$

We identify A with its image in $S(A)$ and let $\iota: A \rightarrow S(A)$ be the inclusion map. Thus we have

$$A = S^0(A) + S^1(A) = R + A_+.$$

We now want to show that the differential of A can be extended to a differential on $S(A)$, giving it the structure of DG R -algebra centered at R .

Theorem 3.1. *The differential of A extends to a differential on $S(A)$ giving it the structure of a DG R -algebra centered at R . Furthermore, $S(A)$ satisfies the following universal mapping property: for every chain map $\varphi: A \rightarrow B$ such that $\varphi(1) = 1$ where B is a DG R -algebra centered at R , there exists a unique DG R -algebra homomorphism $\tilde{\varphi}: S(A) \rightarrow B$ such that $\tilde{\varphi}\iota = \varphi$. We express this in terms of a commutative diagram as below:*

$$\begin{array}{ccc} A & \xrightarrow{\iota} & S(A) \\ & \searrow \varphi & \downarrow \tilde{\varphi} \\ & & B \end{array} \quad (29)$$

Proof. Let d be the differential of A . We first extend d to an R -linear map $U(A) \rightarrow U(A)$, which we denote by d again, which is graded of degree -1 with respect to homological degree as follows: for all elementary tensors of the form (28), we set

$$d(1^{\otimes k} \otimes a_1 \otimes \cdots \otimes a_m) = 1^{\otimes k} \otimes \sum_{j=1}^m (-1)^{|a_1|+\cdots+|a_{j-1}|} a_1 \otimes \cdots \otimes da_j \otimes \cdots \otimes a_m,$$

and we extend d R -linearly everywhere else. It is clear that d is R -linear, graded of degree -1 with respect to the homological degree, and that $d|_A$ is the differential of A . Furthermore, for any elementary tensor of the form (28), we have

$$\begin{aligned} d^2(1^{\otimes k} \otimes a_1 \otimes \cdots \otimes a_m) &= 1^{\otimes k} \otimes \sum_{j=1}^m (-1)^{|a_1|+\cdots+|a_{j-1}|} d(a_1 \otimes \cdots \otimes da_j \otimes \cdots \otimes a_m) \\ &= 1^{\otimes k} \otimes \sum_{1 \leq i < j \leq m} (-1)^{|a_i|+\cdots+|a_{j-1}|} (a_1 \otimes \cdots \otimes da_i \otimes \cdots \otimes da_j \otimes \cdots \otimes a_m) \\ &\quad - 1^{\otimes k} \otimes \sum_{1 \leq j < k \leq m} (-1)^{|a_j|+\cdots+|a_{k-1}|} (a_1 \otimes \cdots \otimes da_j \otimes \cdots \otimes da_k \otimes \cdots \otimes a_m) \\ &= 0. \end{aligned}$$

It follows that $d^2 = 0$, and thus d is indeed a differential. Observe that the differential maps \mathfrak{t} to itself since if $a \in A$, then we have

$$d(1 \otimes a - a) = 1 \otimes da - da \in \mathfrak{t}.$$

Thus d induces a differential on $T(A)$, which we again denote by d . Similarly, observe that d maps \mathfrak{s} to itself since if $a_1, a_2 \in A_+$ are homogeneous, then we have

$$d[a_1, a_2]_{\sigma} = [da_1, a_2]_{\sigma} + (-1)^{|a_1|} [a_1, da_2]_{\sigma} \in \mathfrak{s}.$$

Thus the differential d induces a differential on $S(A)$, which we again denote by d , giving $S(A)$ the structure of a DG R -algebra centered at R where the inclusion map $\iota: A \rightarrow S(A)$ is a chain map which satisfies $\iota(1) = 1$.

Now suppose that $\varphi: A \rightarrow B$ is a chain map such that $\varphi(1) = 1$ where B is a DG R -algebra centered at R . We define $\tilde{\varphi}: S(A) \rightarrow B$ by setting $\tilde{\varphi}(1) = 1$ and

$$\tilde{\varphi}(a_1 \cdots a_m) = \varphi(a_1) \cdots \varphi(a_m) \tag{30}$$

for all elementary products $a_1 \cdots a_m$ in $S(A)$ and then extending it R -linearly everywhere else. By construction, $\tilde{\varphi}$ is multiplicative and satisfies $\tilde{\varphi}(1) = 1$. It also clearly extends $\varphi: A \rightarrow B$. Furthermore, $\tilde{\varphi}$ is a chain map since it is a graded R -linear map which commutes with the differential. Indeed, we clearly have $\tilde{\varphi}d(1) = 0 = d\tilde{\varphi}(1)$, and for all elementary products $a_1 \cdots a_m$ in $S(A)$, we also have

$$\begin{aligned} \tilde{\varphi}d(a_1 \cdots a_m) &= \sum_{j=1}^m (-1)^{|a_1|+\cdots+|a_{j-1}|} \tilde{\varphi}(a_1 \cdots d(a_j) \cdots a_m) \\ &= \sum_{j=1}^m (-1)^{|a_1|+\cdots+|a_{j-1}|} \varphi(a_1) \cdots \varphi d(a_j) \cdots \varphi(a_m) \\ &= \sum_{j=1}^m (-1)^{|a_1|+\cdots+|a_{j-1}|} \varphi(a_1) \cdots d\varphi(a_j) \cdots \varphi(a_m) \\ &= d(\varphi(a_1) \cdots \varphi(a_m)) \\ &= d\tilde{\varphi}(a_1 \cdots a_m). \end{aligned}$$

Finally, if $\tilde{\varphi}': S(A) \rightarrow B$ were another DG R -algebra homomorphism which extended $\varphi: A \rightarrow B$, then we'd have

$$\tilde{\varphi}'(a_1 \cdots a_m) = \tilde{\varphi}'(a_1) \cdots \tilde{\varphi}'(a_m) = \varphi(a_1) \cdots \varphi(a_m) = \tilde{\varphi}(a_1 \cdots a_m)$$

for all elementary products $a_1 \cdots a_m$ in $S(A)$, which implies $\tilde{\varphi}' = \tilde{\varphi}$. \square

3.2 A Presentation of the Maximal Associative Quotient

We now equip A with a multiplication μ , giving it the structure of an MDG R -algebra. The R -bilinear map $A \times A \rightarrow A$ corresponding to μ will be denoted by \star (so as to not confuse it with the multiplication \cdot of $S(A)$). In particular, note that if $a_1, a_2 \in A_1$, then

$$a_1 a_2 \in S_2^2(A), \quad a_1 \star a_2 \in S_2^1(A), \quad \text{and} \quad a_1 a_2 - a_1 \star a_2 \in S_2(A)$$

Note that the multiplier of $\iota: A \rightarrow S(A)$ has the form

$$[a_1, a_2] = \iota(a_1 \star a_2) - \iota(a_1)\iota(a_2) = a_1 \star a_2 - a_1 a_2$$

for all $a_1, a_2 \in A$. Let \mathfrak{b} be the DG $S(A)$ -ideal generated by the multiplier complex $[B]_\iota$. Since B is associative, we have

$$\mathfrak{b} = \text{span}_B \{[a_1, a_2] \mid a_1, a_2 \in A\}.$$

Let $\rho_1: A \rightarrow A/\langle A \rangle$ and $\rho_2: S(A) \rightarrow S(A)/\mathfrak{b}$ denote the corresponding quotient maps.

Theorem 3.2. *With the notation as above, we have $\langle A \rangle = A \cap \mathfrak{b}$. In particular, the composite $\rho_2 \iota: A \rightarrow S(A) \rightarrow S(A)/\mathfrak{b}$ induces an isomorphism $A/\langle A \rangle \simeq S(A)/\mathfrak{b}$ of DG R -algebras.*

Proof. Note that the composite map $\rho_2 \iota: A \rightarrow S(A) \rightarrow S(A)/\mathfrak{b}$ is a surjective MDG R -algebra homomorphism. Since $S(A)/\mathfrak{b}$ is associative, it follows from the universal mapping property of the maximal associative quotient of A that $\ker(\rho_2 \iota) = A \cap \mathfrak{b}$ contains $\langle A \rangle$. Conversely, since $A/\langle A \rangle$ is associative, it follows from the universal mapping property of the symmetric DG algebra that there exists a unique DG R -algebra homomorphism $\tilde{\rho}_1: S(A) \rightarrow A/\langle A \rangle$ which extends $\rho_1: A \rightarrow A/\langle A \rangle$. In particular, note that for $a_1, a_2 \in A$ we have

$$\begin{aligned} \tilde{\rho}_1[a_1, a_2] &= \tilde{\rho}_1(a_1 \star a_2 - a_1 a_2) \\ &= \rho_1(a_1 \star a_2) - \tilde{\rho}_1(a_1 a_2) \\ &= \rho_1(a_1) \star \rho_1(a_2) - \rho_1(a_1) \star \rho_1(a_2) \\ &= 0. \end{aligned}$$

since $\rho_1: A \rightarrow A/\langle A \rangle$ is multiplicative. It follows that $\mathfrak{b} \subseteq \ker \tilde{\rho}_1$, and since $A \cap \ker \tilde{\rho}_1 = \ker \rho_1 = \langle A \rangle$, it follows that $A \cap \mathfrak{b} \subseteq \langle A \rangle$. \square

Remark 6. The isomorphism $A/\langle A \rangle \simeq S(A)/\mathfrak{b}$ is natural in A , meaning if $\varphi: A \rightarrow A'$ is an MDG R -algebra homomorphism where A' is an MDG R -algebra centered at R , then we obtain a commutative diagram:

$$\begin{array}{ccccc} A & \xrightarrow{\iota} & S(A) & \xrightarrow{\pi} & S(A)/\mathfrak{b} \\ \varphi \downarrow & & \tilde{\varphi} \downarrow & & \bar{\varphi} \downarrow \\ A' & \xrightarrow{\iota'} & S(A') & \xrightarrow{\pi'} & S(A')/\mathfrak{b}' \end{array}$$

where we set \mathfrak{b}' to be the DG $S(A')$ -ideal generated by the multiplier complex $[S(A')]_{\iota'}$. Indeed, the map $\tilde{\varphi}: S(A) \rightarrow S(A')$ is the unique DG R -algebra which extends the composite $\iota' \varphi: A \rightarrow S(A')$. Since $\tilde{\varphi}$ is multiplicative, it takes $[S(A)]_\iota$ to $[S(A')]_{\iota'}$ and thus takes \mathfrak{b} to \mathfrak{b}' . In particular, it induces a well-defined map $\bar{\varphi}: S(A)/\mathfrak{b} \rightarrow S(A')/\mathfrak{b}'$.

3.3 The Symmetric DG Algebra of a Finite Free Resolution

In this subsection, we assume that R is a regular local ring (hence an integral domain) with quotient field K . Let F be an R -free resolution of a cyclic R -module with $F_0 = R$. In particular, the underlying graded R -module of F is a finite and free as an R -module. Let e_1, \dots, e_n be an ordered homogeneous basis of F_+ as a graded R -module which is ordered in such a way that if $|e_j| > |e_i|$, then $j > i$. We denote by $R[e] = R[e_1, \dots, e_n]$ to be the free *non-strict* graded-commutative R -algebra generated by e_1, \dots, e_n . In particular, if e_i and e_j are distinct, then we have

$$e_i e_j = (-1)^{|e_i||e_j|} e_j e_i,$$

in $R[e]$, however odd elements do not square to zero in $R[e]$. The reason we do not allow odd elements to square to zero is because later on we want to calculate the Gröbner basis of an ideal of $K[e]$, and the theory of Gröbner bases for $K[e]$ is simpler when we don't have any zerodivisors. It is straightforward to check that

$$R[e]/\langle \{e_i^2 \mid e_i \text{ is odd}\} \rangle \simeq S(F).$$

As usual, we identify F with $R + Re_1 + \dots + Re_n$ and let $\iota: F \rightarrow R[e]$ denote the inclusion map. We extend the differential of F to a differential on $R[e]$ just as we did before giving $R[e]$ the structure of a DG R -algebra so that $\iota: F \rightarrow R[e]$ can be viewed as a chain map which satisfies $\iota(1) = 1$.

Monomials in $R[e]$ are expressed in the form

$$e^\alpha = e_1^{\alpha_1} \cdots e_n^{\alpha_n},$$

where $\alpha = (\alpha_1, \dots, \alpha_n) \in \mathbb{N}^n$ is called the **multidegree** of e^α and is denoted $\text{multideg}(e^\alpha) = \alpha$. Similarly we define its **total degree**, denoted $\deg(e^\alpha)$, and its **homological degree** denoted $|e^\alpha|$, by

$$\deg(e^\alpha) = \sum_{i=1}^n \alpha_i \quad \text{and} \quad |e^\alpha| = \sum_{i=1}^n \alpha_i |e_i|.$$

We equip $R[e]$ with a weighted lexicographical ordering $>$ with respect to the weighted vector $(|e_1|, \dots, |e_n|)$. More specifically, given two monomials e^α and e^β in $R[e]$, we say $e^\alpha > e^\beta$ if either

1. $|e^\alpha| > |e^\beta|$ or;
2. $|e^\alpha| = |e^\beta|$ and there exists $1 \leq i \leq n$ such that $\alpha_i > \beta_i$ and $\alpha_1 = \beta_1, \alpha_2 = \beta_2, \dots, \alpha_{i-1} = \beta_{i-1}$.

The reason we equip $R[e]$ with this choice of monomial ordering will soon become apparent. Given a nonzero polynomial $f \in R[e]$, there exists unique $r_1, \dots, r_m \in R \setminus \{0\}$ and unique $\alpha_1, \dots, \alpha_m \in \mathbb{N}^n$ where $\alpha_i \neq \alpha_j$ for all $1 \leq i < j \leq m$ such that

$$f = r_1 e^{\alpha_1} + \dots + r_m e^{\alpha_m}. \quad (31)$$

We call (??) the **canonical representation** of f . The $r_i e^{\alpha_i}$ in (??) are called the **terms** of f , and the e^{α_i} in (??) are called the **monomials** of f . By reindexing the α_i if necessary, we may assume that $e^{\alpha_1} > \dots > e^{\alpha_m}$. In this case, we call $r_1 e^{\alpha_1}$ the **lead term** of f , and denote this by $\text{LT}(f) = r_1 e^{\alpha_1}$. Similarly we call r_1 the **lead coefficient** of f and we call e^{α_1} the **lead monomial** of f , and we denote these by $\text{LC}(f) = r_1$ and $\text{LM}(f) = e^{\alpha_1}$ respectively. The **multidegree** of f is defined to be the multidegree of its lead monomial e^{α_1} and is denoted $\text{multideg}(f) = \alpha_1$. The **total degree** of f is defined to be the maximum of the total degrees of its monomials and is denoted $\deg(f) = \max_i \{\deg(e^{\alpha_i})\}$. We say f is **homogeneous** of degree i if each monomial of f has homological degree i , and in this case, we say f has **homological degree** i , and denote this by $|f| = i$.

3.3.1 Multiplications Induced by Projections

We now want to explain how *all* multiplications on F come from projections $S(F) \rightarrow F$.

Definition 3.1. A **projection** from $S(F)$ to F is a surjective chain map $\pi: S(F) \rightarrow F$ which splits the inclusion map $\iota: F \rightarrow S(F)$, meaning $\pi \iota = 1_A$. We denote by $\mathcal{P}(S(F), F)$ to be the set of all projections from $S(F)$ to F .

Let (ν, \cdot) denote the multiplication of $S(F)$. Given a projection $\pi: S(F) \rightarrow F$, we define a multiplication (μ_π, \star_π) on F , by setting $\mu_\pi := \pi \nu$. In other words, we have

$$a_1 \star_\pi a_2 := \pi(a_1 a_2)$$

for all $a_1, a_2 \in F$. We refer to μ_π as the **multiplication induced by π** . Thus we have a map $\mathcal{P}(S(F), F) \rightarrow \text{Mult}(F)$ given by $\pi \mapsto \mu_\pi$. The next proposition tells us that this map is actually surjective.

Proposition 3.1. Let (μ, \star) be a multiplication on F . There exists a projection $\pi: S(F) \rightarrow F$ such that $\mu = \mu_\pi$.

Proof. We first define $\pi: S(F) \rightarrow F$ on elementary products of the form $e_{i_1} \cdots e_{i_k}$ where $e_{i_1} \leq \dots \leq e_{i_k}$. For each $0 \leq i \leq n$, we set $\pi(e_i) = e_i$ for all $1 \leq i \leq n$. For each $0 \leq i_1, i_2 \leq n$, we set $\pi(e_{i_1} e_{i_2}) = e_{i_1} \star e_{i_2}$. For each $0 \leq i_1, i_2, i_3 \leq n$, we set $\pi(e_{i_1} e_{i_2} e_{i_3}) = (e_{i_1} \star e_{i_2}) \star e_{i_3}$. More generally, for each $0 \leq i_1, \dots, i_k \leq n$ where $k \geq 4$, we set

$$\pi(e_{i_1} e_{i_2} e_{i_3} \cdots e_{i_k}) := (((\cdots (e_{i_1} \star e_{i_2}) \star e_{i_3}) \star \cdots) \star e_{i_k}), \quad (32)$$

We then extend π everywhere else R -linearly. It is straightforward to check that $\mu = \mu_\pi$. \square

Remark 7. Note that if (μ, \star) is not associative, then (32) depends on a choice of parenthesization. Thus if (μ, \star) is not associative, then there's usually more than one projection $S(F) \rightarrow F$ which induces the multiplication.

3.3.2 Gröbner Basis Calculations

We now equip F with a multiplication (μ, \star) which is induced by the projection $\pi: S(F) \rightarrow F$. In this subsection, we will show how to calculate the maximal associative quotient of F using the theory of Gröbner bases for $K[e]$. For each $1 \leq i, j \leq n$, let $f_{i,j}$ be the polynomial in $R[e]$ defined by $f_{i,j} := -[e_i, e_j]$. Thus we have

$$f_{i,j} = e_i e_j - \sum_k r_{i,j}^k e_k = e_i e_j - e_i \star e_j.$$

Let $\mathcal{F} = \{f_{i,j} \mid 1 \leq i, j \leq n\}$ and let \mathfrak{b} be the DG $R[e]$ -ideal generated by \mathcal{F} . Note that if e_i is odd, then $f_{i,i} = e_i^2$ since \star is strictly graded-commutative, thus $R[e]/\mathfrak{b} \simeq F/\langle F \rangle$ by Theorem (3.2). Recall that $R[e]$ comes equipped with a monomial ordering which we defined earlier.

Lemma 3.3. For each $1 \leq i, j \leq n$, we have

$$\text{LT}(f_{i,j}) = e_i e_j.$$

Proof. If $e_i \star e_j = 0$, then this is clear, otherwise term of $e_i \star e_j$ has the form $r_{i,j}^k e_k$ for some k where $r_{i,j}^k \neq 0$. Since \star respects homological degree, we have $|e_k| = |e_i| + |e_j| = |e_i e_j|$. It follows that $|e_k| > |e_i|$ and $|e_k| > |e_j|$ since $|e_i|, |e_j| \geq 1$. This implies $k > i$ and $k > j$ by our assumption on the ordering of e_1, \dots, e_n . Therefore since $|e_i e_j| = |e_k|$ and $k > i$, we see that $e_i e_j > e_k$. \square

Lemma 3.4. Let e^α be a monomial in $R[e]$. Express e^α in the form $e^\alpha = e_m^{\alpha_m} e^{\tilde{\alpha}}$ where $e_m > e_j$ for all $e_j \in \text{supp}(e^{\tilde{\alpha}})$. Then

$$\text{LM}(de^\alpha) = e_m^{\alpha_m} \text{LM}(de^{\tilde{\alpha}}) = e_m^{\alpha_m} e^\gamma$$

where we set $e^\gamma = \text{LM}(de^{\tilde{\alpha}})$. Moreover, we have $e_m > e_i$ for all $e_i \in \text{supp}(e^\gamma)$.

Proof. By the Leibniz law, we have

$$\begin{aligned} de^\alpha &= d(e_m^{\alpha_m} e^{\tilde{\alpha}}) \\ &= d(e_m^{\alpha_m}) e^{\tilde{\alpha}} + (-1)^{|e_m^{\alpha_m}|} e_m^{\alpha_m} d(e^{\tilde{\alpha}}). \\ &= \alpha_m e_m^{\alpha_m-1} d(e_m) e^{\tilde{\alpha}} + (-1)^{|e_m^{\alpha_m}|} e_m^{\alpha_m} d(e^{\tilde{\alpha}}) \end{aligned}$$

The monomials of $\alpha_m e_m^{\alpha_m-1} d(e_m) e^{\tilde{\alpha}}$ have the form $e_m^{\alpha_m-1} e_k e^{\tilde{\alpha}}$, where necessarily we have $e_m > e_k$ since $|e_m| > |e_k|$. It follows that

$$e_m^{\alpha_m} e^\gamma > e_m^{\alpha_m-1} e_k e^{\tilde{\alpha}}$$

for all monomials $e_m^{\alpha_m-1} e_k e^{\tilde{\alpha}}$ of $\alpha_m e_m^{\alpha_m-1} d(e_m) e^{\tilde{\alpha}}$. Similarly, the monomials of $e_m^{\alpha_m} d(e^{\tilde{\alpha}})$ have the form $e_m^{\alpha_m} e^\beta$ where e^β is a monomial of $d(e^{\tilde{\alpha}})$. Since e^γ is the lead monomial of $d(e^{\tilde{\alpha}})$, we have

$$e_m^{\alpha_m} e^\gamma > e_m^{\alpha_m} e^\beta$$

for all monomials $e_m^{\alpha_m} e^\beta$ of $e_m^{\alpha_m} d(e^{\tilde{\alpha}})$. Note that e^γ has the form $\pm e_j e^{\tilde{\alpha}}$ where e_j is a monomial of $d(e_k)$ where $\pm e_k e^{\tilde{\alpha}} = e^{\tilde{\alpha}}$. In particular, we must have $e_m > e_k > e_j$ since $|e_k| > |e_j|$. It follows that $e_m > e_i$ for all $e_i \in \text{supp}(e^\gamma)$ since

$$\text{supp}(e^\gamma) \subseteq \text{supp}(e^{\tilde{\alpha}}) \cup \{e_j\}.$$

Moreover, note that $e_m^{\alpha_m} e^{\beta_0} \geq e_m^{\alpha_m-1} e^{\tilde{\alpha}}$ since they both have the same homological degree and since $e_m > e_i$ for all $e_i \in \text{supp}(e^{\tilde{\alpha}})$. \square

Lemma 3.5. Let e^β and e^α be monomials in $R[e]$ such that $e^\beta > e^\alpha$. Then

$$\text{LM}(de^\beta) > \text{LM}(de^\alpha).$$

Proof. We may assume that $|e^\beta| = |e^\alpha|$. Express e^β and e^α in the form

$$e^\beta = e_m^{\beta_m} e^{\tilde{\beta}} \text{ and } e^\alpha = e_l^{\alpha_l} e^{\tilde{\alpha}}$$

where $e_m > e_j$ for all $e_j \in \text{supp}(e^{\tilde{\beta}})$ and where $e_l > e_i$ for all $e_i \in \text{supp}(e^{\tilde{\alpha}})$. Let e^δ be the lead monomial of $d(e^{\tilde{\beta}})$ and let e^γ be the lead monomial of $d(e^{\tilde{\alpha}})$. Thus $e_m^{\beta_m} e^\delta$ is the lead monomial of $d(e^\beta)$ and $e_l^{\alpha_l} e^\gamma$ is the lead monomial of $d(e^\alpha)$ and we need to show:

$$e_m^{\beta_m} e^\delta > e_l^{\alpha_l} e^\gamma \quad (33)$$

Since $e^\beta > e^\alpha$ and $|e^\beta| = |e^\alpha|$, either $e_m > e_l$ or $e^{\tilde{\beta}} > e^{\tilde{\alpha}}$. If $e_m > e_l$, then we get (33) since both sides have the same homological degree and since $e_m > e_i$ for all $e_i \in \text{supp}(e_l^{\alpha_l} e^\gamma)$. Thus we may assume that $e_m^{\beta_m} = e_l^{\alpha_l}$ and $e^{\tilde{\beta}} > e^{\tilde{\alpha}}$. Then an argument by induction on the total degree gives us $e^\delta > e^\gamma$, and so we again obtain (33). \square

In order to study $R[e]/\mathfrak{b} \simeq F/\langle F \rangle$, we first pass to the quotient field K and study $K[e]/\mathfrak{b}_K = F_K/\langle F_K \rangle$ where $\mathfrak{b}_K \simeq K \otimes_R \mathfrak{b}$ and $F_K \simeq K \otimes_R F$ (we view \mathfrak{b}_K as the $K[e]$ -ideal generated by \mathfrak{b}) so that we can use tools from the theory of Gröbner bases for $K[e]$. In particular, we wish to construct a left Gröbner basis for \mathfrak{b}_K (which will in fact be a two-sided Gröbner basis) using the weighted lexicographical ordering that we defined above. Our main reference in what follows is [GP02]. Suppose f, g are two nonzero polynomials in $K[e]$ with $\text{LT}(f) = re^\alpha$ and $\text{LT}(g) = se^\beta$. Set $\gamma = \text{lcm}(\alpha, \beta)$ and define the left **S-polynomial** of f and g to be

$$\text{S}(f, g) = e^{\gamma-\alpha} f \pm (r/s) e^{\gamma-\beta} g \quad (34)$$

where the \pm in (34) is chosen to be $+$ or $-$, depending on which sign will cancel out the lead terms. We begin Buchberger's algorithm by calculating the S-polynomials of all pairs of polynomials in \mathcal{F} . In other words, we calculate all S-polynomials of the form $S(f_{k,l}, f_{i,j})$ where $1 \leq i, j, k, l \leq n$. Note that if $k > l$, then

$$f_{l,k} = (-1)^{|e_k||e_l|} f_{k,l},$$

which implies

$$S(f_{l,k}, f_{i,j}) = (-1)^{|e_k||e_l|} S(f_{k,l}, f_{i,j}) = \pm S(f_{i,j}, f_{k,l}).$$

Similarly, if $i \geq k$, then

$$S(f_{i,j}, f_{l,k}) = \pm S(f_{k,l}, f_{i,j}).$$

Thus we may assume that $j \geq i$ and $l \geq k \geq i$. Obviously we have $S(f_{i,j}, f_{i,j}) = 0$ for each i, j , however something interesting happens when we calculate the S-polynomial of $f_{j,k}$ and $f_{i,j}$ where $j > i$ and then divide this by \mathcal{F} (where division by \mathcal{F} means taking the left normal form of $S(f_{j,k}, f_{i,j})$ with respect to \mathcal{F} using the left normal form described in [GP02]). We have

$$\begin{aligned} S(f_{j,k}, f_{i,j}) &= e_i(e_j e_k - e_j \star e_k) - (e_i e_j - e_i \star e_j) e_k \\ &= (e_i \star e_j) e_k - e_i(e_j \star e_k) \\ &= \sum_l r_{i,j}^l e_l e_k - \sum_l r_{j,k}^l e_i e_l \\ &\rightarrow \sum_l r_{i,j}^l e_l \star e_k - \sum_l r_{j,k}^l e_i \star e_l \\ &= (e_i \star e_j) \star e_k - e_i \star (e_j \star e_k) \\ &= [e_i, e_j, e_k], \end{aligned}$$

where in the fourth line we did division by \mathcal{F} (note that if $[e_i, e_j, e_k] \neq 0$, then $\deg([e_i, e_j, e_k]) = 1$, so we cannot divide this anymore by \mathcal{F}). Finally if $j > i$, $l > k$, and $j \neq k$, then we have

$$\begin{aligned} S(f_{k,l}, f_{i,j}) &= e_i e_j f_{k,l} - f_{i,j} e_k e_l \\ &= (e_i \star e_j) e_k e_l - e_i e_j (e_k \star e_l) \\ &\rightarrow (e_i \star e_j) \star (e_k \star e_l) - (e_i \star e_l) \star (e_k \star e_l) \\ &= 0 \end{aligned}$$

where in the third line we did division by \mathcal{F} . Next, suppose that

$$f = r e_k + r' e_{k'} + \cdots + r'' e_{k''} \in \langle F \rangle$$

where $r, r', r'' \in R$ with $r \neq 0$ and where $\text{LM}(f) = e_k$. Then we have

$$\begin{aligned} S(f, f_{j,k}) &= e_j f - r f_{j,k} \\ &= r' e_j e_{k'} + \cdots + r'' e_j e_{k''} + r e_j \star e_k \\ &\rightarrow r' e_j \star e_{k'} + \cdots + r'' e_j \star e_{k''} + r e_j \star e_k \\ &= e_j \star (r e_k + r' e_{k'} + \cdots + r'' e_{k''}) \\ &= e_j \star f \\ &\in \langle F \rangle \end{aligned}$$

where in the third line we did division by \mathcal{F} . Similarly, we have if $i \neq k \neq j$, then we have

$$\begin{aligned} S(f, f_{i,j}) &= e_i e_j f - r f_{i,j} e_k \\ &= r' (e_i e_j) e_{k'} + \cdots + r'' (e_i e_j) e_{k''} + r (e_i \star e_j) e_k \\ &\rightarrow r' (e_i \star e_j) \star e_{k'} + \cdots + r'' (e_i \star e_j) \star e_{k''} + r (e_i \star e_j) \star e_k \\ &= (e_i \star e_j) \star (r e_k + r' e_{k'} + \cdots + r'' e_{k''}) \\ &= (e_i \star e_j) \star f \\ &\in \langle F \rangle. \end{aligned}$$

where in the third line we did division by \mathcal{F} . Finally suppose that

$$g = s e_m + s' e_{m'} + \cdots + s'' e_{m''} \in \langle F \rangle$$

where $s, s', s'' \in R$ with $s \neq 0$ and where $\text{LM}(g) = e_m$. If $k = m$, then we have

$$sS(f, g) = sf - rg \in \langle F \rangle.$$

On the other hand, if $k \neq m$, then we have

$$\begin{aligned} sS(f, g) &= se_m f - rge_k \\ &= sr'e_m e_{k'} + \cdots + sr''e_m e_{k''} - rs'e_{m'} e_k - \cdots - rs''e_{m''} e_k \\ &\rightarrow sr'e_m \star e_{k'} + \cdots + sr''e_m \star e_{k''} - rs'e_{m'} \star e_k - \cdots - rs''e_{m''} \star e_k \\ &= se_m \star (r'e_{k'} + \cdots + r''e_{k''}) - r(s'e_{m'} + \cdots + s''e_{m''}) \star e_k \\ &= se_m \star (f - re_k) - r(g - se_m) \star e_k \\ &= se_m \star f + rg \star e_k - sre_m \star e_k + rse_m \star e_k \\ &= se_m \star f + rg \star e_k \\ &\in \langle F \rangle. \end{aligned}$$

It follows that we can construct a Gröbner basis $\mathcal{G} := \mathcal{F} \cup \{g_1, \dots, g_m\}$ of \mathfrak{b}_K such that the g_i all belong to $\langle F \rangle$.

3.3.3 Measuring the Failure to being Associative

Using the Gröbner basis we constructed above, we can measure the failure for F to being associative in degree i . In particular, observe that

$$\begin{aligned} \text{rank}_R(F_i / \langle F \rangle_i) &= \dim_K((F_K / \langle F_K \rangle)_i) \\ &= \dim_K(K[e]_i / \mathfrak{b}_{K,i}) \\ &= \dim_K(F_i) - \#\{e_j \mid |e_j = \text{LM}(f) \text{ for some } f \in \langle F \rangle_i\} \\ &= \text{rank}_R(F_i) - \#\{e_j \mid |e_j = \text{LM}(f) \text{ for some } f \in \langle F \rangle_i\}. \end{aligned}$$

Thus we have

$$\text{rank}_R(F_i) - \text{rank}_R(F_i / \langle F \rangle_i) = \#\{e_j \mid |e_j = \text{LM}(f) \text{ for some } f \in \langle F \rangle_i\}$$

4 Multigraded MDG Algebras

Let $R = \mathbb{k}[x] = \mathbb{k}[x_1, \dots, x_d]$, let $I = \langle \mathbf{m} \rangle = \langle m_1, \dots, m_\ell \rangle$ be a monomial ideal in R , and let F be the minimal R -free resolution of R/I . Choose a multiplication μ on F which respects the multigrading giving it the structure of a multigraded MDG R -algebra. We denote by $\star = \star_\mu$ to be the R -bilinear map corresponding to μ in what follows. Let $e_1, \dots, e_\ell, e_{\ell+1}, \dots, e_n$ be an ordered homogeneous basis of F where each e_i is multigraded with $\text{multideg}(e_i) = m_i$. Recall that for each $1 \leq i, j \leq n$, there exists unique $r_{i,j}^k \in R$ such that

$$e_i \star e_j = \sum_{k=0}^n r_{i,j}^k e_k, \quad (35)$$

Since μ also respects the multigrading, we must have

$$r_{i,j}^k = c_{i,j}^k \frac{m_i m_j}{m_k},$$

where m_i, m_j, m_k are the monomials corresponding to the multidegrees of e_i, e_j, e_k , and where $c_{i,j}^k \in \mathbb{k}$ are called the **structured \mathbb{k} -coefficients** of μ . It would be nice if we could re-express (35) as

$$\left(\frac{e_i}{m_i} \right) \left(\frac{e_j}{m_j} \right) = \sum_k c_{i,j}^k \left(\frac{e_k}{m_k} \right), \quad (36)$$

but the problem is that F does not contain terms like e_i/m_i . In order to make sense of (36), we perform a base change. Namely let S be the multiplicatively closed set generated by $\{m_1, \dots, m_n\}$. We set $\tilde{F} = F_{S,0}$ to be the multidegree $\mathbf{0}$ component of F_S . The \mathbb{N}^n -graded MDG R -algebra structure on F induces an MDG \mathbb{k} -algebra structure on \tilde{F} . The multiplication (36) makes perfect sense in the MDG \mathbb{k} -algebra \tilde{F} . Denoting $\tilde{e}_i = e_i/m_i$ for each i , we can re-express (36) as

$$\tilde{e}_i \tilde{e}_j = \sum_k c_{i,j}^k \tilde{e}_k.$$

Theorem 4.1. *F is a DG R -algebra if and only if \tilde{F} is a DG \mathbb{k} -algebra.*

Proof. A straightforward calculation gives us

$$[e_i, e_j, e_k]_\mu = m_i m_j m_k [\tilde{e}_i, \tilde{e}_j, \tilde{e}_k]_{\tilde{\mu}}$$

for all i, j, k . Thus μ is associative if and only if $\tilde{\mu}$ is associative. \square

4.1 All Multigraded Multiplications Come From the Taylor Resolution

Let T be the Taylor algebra resolution of R/\mathfrak{m} . The Taylor multiplication is denoted ν_T . Let ν be a possibly different multiplication on T . We write T_ν to be the MDG R -algebra whose underlying complex is the same as the underlying complex of T but whose multiplication is ν . Since F is the minimal R -free resolution of R/I and since T is an R -free resolution of R/\mathfrak{m} , there exists multigraded chain maps $\iota: F \rightarrow T$ and $\pi: T \rightarrow F$ which lift the identity map $R/\mathfrak{m} \rightarrow R/\mathfrak{m}$ such that $\iota: F \rightarrow T$ is injective and is split by $\pi: T \rightarrow F$, meaning $\pi\iota = 1$. By identifying F with $\iota(F)$ if necessary, we may assume that $\iota: F \subseteq T$ is inclusion and that $\pi: T \rightarrow F$ is a **projection**, meaning $\pi: T \rightarrow F$ is a surjective chain map which satisfies $\pi^2 = \pi$, or alternatively, $\pi: T \rightarrow T$ is a chain map with $\text{im } \pi = F$. In what follows, we fix $\iota: F \subseteq T$ to be the inclusion map once and for all and we denote by $\mathcal{P}(T, F)$ to be the set of all projections $\pi: T \rightarrow F$. For each $\mu \in \text{Mult}(F)$, we denote by $\text{Mult}(T/\mu)$ to be the set of all multiplications on T which extends μ :

$$\text{Mult}(T/\mu) = \{\nu \in \text{Mult}(T) \mid \nu|_{F^{\otimes 2}} = \nu\iota^{\otimes 2} = \mu\}.$$

Observe that if $\pi \in \mathcal{P}(T, F)$ and $\nu \in \text{Mult}(T/\mu)$, then $\pi\nu \in \text{Mult}(T/\mu)$. Indeed, $\pi\nu$ is clearly a multiplication on T . Furthermore, since π is a projective and since μ lands in F , we have $\pi\mu = \mu$. Therefore

$$\pi\nu\iota^{\otimes 2} = \pi\mu = \mu,$$

so $\pi\nu$ restricts to μ as well. Next, observe that if $\pi \in \mathcal{P}(T, F)$ and $\mu \in \text{Mult}(F)$, then $\hat{\mu}_\pi := \mu\pi^{\otimes 2} \in \text{Mult}(T/\mu)$. We call $\hat{\mu} = \hat{\mu}_\pi$ the **trivial extension** of μ with respect to π for the following reasons: first note that for each $\nu \in \text{Mult}(T/\mu)$, the inclusion map $\iota: F_\mu \subseteq T_\nu$ is multiplicative since $\nu\iota^{\otimes 2} = \mu = \iota\mu$, however $\pi: T_\nu \rightarrow F_\mu$ need not be multiplicative in general. In the case of the trivial extension $\hat{\mu}$ however, $\pi: T_{\hat{\mu}} \rightarrow F_\mu$ is multiplicative since

$$\pi\hat{\mu} = \pi\mu\pi^{\otimes 2} = \mu\pi^{\otimes 2}.$$

Next, note that since $\pi: T \rightarrow F$ splits the inclusion $\iota: F \subseteq T$, we obtain isomorphism $\theta_\pi: T \simeq F \oplus H$ of R -complexes, where $H = \ker \pi$ is a trivial R -complex with $H_0 = 0 = H_1$, and where $\theta_\pi = (\pi, 1 - \pi)$. There's an obvious multiplication that we can give $F \oplus H$, namely $\mu \oplus 0$, where $0: H \otimes H \rightarrow H$ is the zero map. Equip $F \oplus H$ with this multiplication. We claim that $\theta_\pi: T_{\hat{\mu}} \rightarrow F \oplus H$ is multiplicative, and hence an isomorphism of MDG R -algebras. Indeed, we have

$$\begin{aligned} \theta_\pi \hat{\mu} &= (\pi\hat{\mu}, (1 - \pi)\hat{\mu}) \\ &= (\pi\hat{\mu}, \hat{\mu} - \pi\hat{\mu}) \\ &= (\hat{\mu}, \hat{\mu} - \hat{\mu}) \\ &= (\hat{\mu}, 0) \\ &= (\mu\pi^{\otimes 2}, 0) \\ &= (\mu \oplus 0)(\pi^{\otimes 2}, 1 - \pi^{\otimes 2}) \\ &= (\mu \oplus 0)\theta_\pi^{\otimes 2}. \end{aligned}$$

In particular, every $b \in T$ can be expressed in the form $b = a + c$ for unique $a \in F$ and unique $c \in H$. If $b_1, b_2 \in T$ have the unique expressions $b_1 = a_1 + c_1$ and $b_2 = a_2 + c_2$, then we have $b_1 \star_\nu b_2 = a_1 \star_\mu a_2$. It follows that $\langle T_{\hat{\mu}} \rangle = \langle F_\mu \rangle$.

Proposition 4.1. *Assume that no associative multiplication on F exists. Then the Taylor multiplication ν_T does not arise from any multiplication on F .*

Proof. Assume for a contradiction that $\nu_T = \hat{\mu}$ for some multiplication μ on F . Then as noted above, ν_T extends the multiplication μ . In particular, since ν_T is associative, it is necessarily the case that μ is associative too. However this contradicts our assumption that there does not exist any associative multiplication on F . \square

Example 4.1. The multiplication given in Example (1.1) comes from the projection $\pi: T \rightarrow F$ where T is the Taylor algebra resolution of R/\mathfrak{m} and where π is defined by

$$\begin{aligned}\pi(e_{15}) &= yz^2e_{14} + xe_{45} \\ \pi(e_{25}) &= y^2ze_{23} + we_{35} \\ \pi(e_{245}) &= -yze_{234} + we_{35} \\ \pi(e_{235}) &= 0 \\ \pi(e_{2345}) &= 0 \\ &\vdots\end{aligned}$$

and so on.

When a multiplication of T does arise from a multiplication of F , it trivially extends the multiplication of F in the following sense: let ν be a multiplication on T which comes from a multiplication μ on F , so $\nu = \hat{\mu}$. Since $\pi: T \rightarrow F$ splits the inclusion $\iota: F \rightarrow T$, we obtain isomorphism $\theta_\pi: T \simeq F \oplus H$ of R -complexes, where $H = \ker \pi$ is a trivial R -complex with $H_0 = 0 = H_1$, and where $\theta_\pi = (\pi, 1 - \iota\pi)$ (that is, it is given by $b \mapsto (\pi(b), b - \pi(b))$ for all $b \in T$). There's an obvious multiplication that we can give $F \oplus H$, namely $\mu \oplus 0$, where $0: H \otimes H \rightarrow H$ is the zero map. Equip $F \oplus H$ with this multiplication. We claim that $\theta_\pi: T_\nu \rightarrow F \oplus H$ is multiplicative, and hence an isomorphism of MDG R -algebras. Indeed, we have

$$\begin{aligned}\theta_\pi \nu &= (\pi\nu, (1 - \iota\pi)\nu) \\ &= (\mu\pi^{\otimes 2}, \nu - \iota\mu\pi^{\otimes 2}) \\ &= (\mu\pi^{\otimes 2}, 0) \\ &= (\mu \oplus 0)(\pi^{\otimes 2}, 1 - \pi^{\otimes 2}) \\ &= (\mu \oplus 0)\theta_\pi^{\otimes 2}.\end{aligned}$$

In particular, every $b \in T$ can be expressed in the form $b = a + c$ for a unique $a \in F$ and $c \in H$. If $b_1, b_2 \in T$ with unique expressions $b_1 = a_1 + c_1$ and $b_2 = a_2 + c_2$, then we have

$$b_1 \star_\nu b_2 = a_1 \star_\mu a_2.$$

It follows that $\langle T_\nu \rangle = \langle F_\mu \rangle$.

Definition 4.1. Let μ be a multiplication on F . We denote by $\text{Mult}(T/\mu)$ to be the set of all multiplications on T which extends μ :

$$\text{Mult}(T/\mu) = \{\nu \in \text{Mult}(T) \mid \nu|_{F^{\otimes 2}} = \nu\iota^{\otimes 2} = \mu\}.$$

We denote by $\mathcal{P}(T, F)$ to be the set of all chain maps $\pi: T \rightarrow F$ which are projections, meaning π is surjective and satisfies $\pi^2 = \pi$. Observe that if $\pi \in \mathcal{P}(T, F)$ and $\nu \in \text{Mult}(T/\mu)$, then $\pi\nu \in \text{Mult}(T/\mu)$. Indeed, $\pi\nu = \hat{\mu}\pi$.

$$\begin{array}{ccc} T \otimes_R T & \xrightarrow{\nu} & T \\ \pi^{\otimes 2} \downarrow & & \downarrow \pi \\ F \otimes_R F & \xrightarrow{\mu} & F \\ \tau^{\otimes 2} \downarrow & & \downarrow \tau \\ R/I \otimes_R R/I & \xrightarrow{\mathfrak{m}} & R/I \end{array} \quad (37)$$

5 The Associator Functor

Let X and Y be MDG A -modules and let $\varphi: X \rightarrow Y$ be a chain map. If φ is multiplicative, then observe that for all $a_1, a_2, a_3 \in A$ and $x \in X$, we have

$$\varphi(a_1[a_2, a_3, x]) = a_1[a_2, a_3, \varphi(x)]. \quad (38)$$

Thus φ restricts to an MDG A -module homomorphism $\varphi: \langle X \rangle \rightarrow \langle Y \rangle$. In particular, the assignment $X \mapsto \langle X \rangle$ induces a functor from category of MDG A -modules to itself. We call this the **associator functor**.

5.1 Failure of Exactness

The associator functor need not be exact. Indeed, let

$$0 \longrightarrow X \xrightarrow{\varphi} Y \xrightarrow{\psi} Z \longrightarrow 0 \quad (39)$$

be a short exact sequence of MDG A -modules. We obtain an induced sequence of MDG A -modules

$$0 \longrightarrow \langle X \rangle \xrightarrow{\varphi} \langle Y \rangle \xrightarrow{\psi} \langle Z \rangle \longrightarrow 0 \quad (40)$$

which is exact at $\langle X \rangle$ and $\langle Z \rangle$ but not necessarily exact at $\langle Y \rangle$. In order to ensure exactness of (40), we need to place a condition on (39). This leads us to consider the following definition:

Definition 5.1. Let X be an MDG A -submodule of Y . We say Y is an **associative extension** of X if it satisfies

$$\langle X \rangle = X \cap \langle Y \rangle.$$

It is easy to see that (40) is a short exact sequence of MDG A -modules if and only if Y is an associative extension of X . In this case, we obtain a long exact sequence in homology:

$$\begin{array}{ccccccc} & & & \cdots & \longrightarrow & H_{i+1}\langle Z \rangle & \\ & & & & & \downarrow & \\ & & & & & H_i\langle X \rangle & \longrightarrow & H_i\langle Y \rangle & \longrightarrow & H_i\langle Z \rangle & \\ & & & & & \downarrow & \\ & & & & & H_{i-1}\langle X \rangle & \longrightarrow & \cdots \end{array} \quad (41)$$

We can use this long exact sequence to deduce interesting theorems like:

Theorem 5.1. Let X be an MDG A -module and suppose Y is an associative extension of X . Then Y is homologically associative if and only if X and Y/X are homologically associative.

5.2 An Application of the Long Exact Sequence

We want to discuss another application of the long exact sequence (41). Suppose that (R, \mathfrak{m}) is a local ring. Let $I \subseteq \mathfrak{m}$ be an ideal of R , let F be the minimal R -free resolution of R/I which is equipped with a multiplication μ giving it the structure of an MDG R -algebra, and let $r \in \mathfrak{m}$ be an (R/I) -regular element. Then the mapping cone $F + eF$ is the minimal R -free resolution of $R/\langle I, r \rangle$. Here, e is thought of as an exterior variable of degree 1. The differential of the mapping cone is given by

$$d(a + eb) = d(a) + rb - ed(b)$$

for all $a, b \in F$. We give $F + eF$ the structure of an MDG R -algebra by extending the multiplication on F to a multiplication on $F + eF$ by setting

$$(a + eb)(c + ed) = ac + e(bc + (-1)^{|a|}ad)$$

for all $a, b, c, d \in F$. In particular, note that $(eb)c = e(bc)$ for all $b, c \in F$, so e belongs to the nucleus of $F + eF$. We denote by $\iota: F \rightarrow F + eF$ to be the inclusion map. We can view $F + eF$ either as an MDG F -module or as an MDG R -algebra, thus we potentially two different associator complexes to consider. In fact, it turns out that these give rise to the same R -complex since e is in the nucleus of $F + eF$, as the next lemma will show.

Lemma 5.2. Let $\langle F + eF \rangle_A$ be the associator A -submodule of $F + eF$ and let $\langle F + eF \rangle$ be the associator $(F + eF)$ -ideal. Then

$$\langle F + eF \rangle_A = e\langle F \rangle = \langle F + eF \rangle. \quad (42)$$

In particular, $F + eF$ is an associative extension of F .

Proof. Since e is in the nucleus, we have $e[a, b, c] = [ea, b, c]$ for all $a, b, c \in F$. Similarly we have

$$\begin{aligned} [a, b, ec] &= -(-1)^{|a||b|+|a||ec|+|ec||b|}[ec, b, a] \\ &= -(-1)^{|a||b|+|a||c|+|b||c|}[ec, b, a] \\ &= -(-1)^{|a||b|+|a||c|+|b||c|}e[c, b, a] \\ &= e[a, b, c] \end{aligned}$$

for all $a, b, c \in F$. Similarly we have

$$\begin{aligned} [a, eb, c] &= -(-1)^{|a||eb|+|a||c|}[eb, c, a] - (-1)^{|eb||c|+|a||c|}[c, a, eb] \\ &= e(-(-1)^{|a||eb|+|a||c|}[b, c, a] - (-1)^{|eb||c|+|a||c|}[c, a, b]) \\ &= e[a, b, c] \end{aligned}$$

for all $a, b, c \in F$. Thus we have

$$\begin{aligned} (a + ea')[b + eb', c + ec', d + ed'] &= (a + ea')[b, c, d] + (a + ea')(e[b', c', d']) \\ &= a[b, c, d] + ea'[b, c, d] + (-1)^{|a|}ea[b', c', d'] \\ &= a[b, c, d] + e(a'[b, c, d] + (-1)^{|a|}a[b', c', d']) \end{aligned}$$

for all $a, b, c, d, a', b', c', d' \in F$. Thus we have (42). To see why (42) implies $F + eF$ is an associative extension of F , note that

$$F \cap \langle F + eF \rangle = F \cap e\langle F \rangle = \langle F \rangle.$$

□

Since $F + eF$ is an associative extension of F , we obtain a long exact sequence of the form:

$$\begin{array}{ccccccc} & & \cdots & \longrightarrow & H_i\langle F \rangle & & \\ & & & & \downarrow r & & \\ & \swarrow & & & & & \\ H_i\langle F \rangle & \longrightarrow & H_i\langle F + eF \rangle & \longrightarrow & H_{i-1}\langle F \rangle & & \\ & & & & \downarrow r & & \\ & \swarrow & & & & & \\ & H_{i-1}\langle F \rangle & \longrightarrow & \cdots & & & \end{array} \quad (43)$$

It follows from long exact sequence in homology (43) together with Nakayama's lemma that

$$\text{lha}(F + eF) = \text{lha}(F).$$

On the the other hand, we have

$$\text{uha}(F + eF) = \begin{cases} \text{uha}(F) & \text{if } r \text{ is } H_\delta\langle F \rangle\text{-regular} \\ \text{uha}(F) + 1 & \text{otherwise} \end{cases}$$

Appendix

6 Localization, Tensor, and Hom

Let A be an MDG R -algebra and let X and Y be MDG A -modules. In this subsection we define the tensor complex $X \otimes_A Y$ (which turns out to be an MDG A -module with the obvious A -scalar multiplication) as well as the hom complex $\text{Hom}_A^*(X, Y)$ (which need not be an MDG A -module using the naive A -scalar multiplication since this map need not be well-defined). Before defining these complexes however, we first discuss localization.

6.1 Localization

A subset $S \subseteq A$ is called **multiplicatively closed** if it satisfies the following conditions:

1. We have $1 \in S$ and if $s_1, s_2 \in S$ we have $s_1 s_2 \in S$.
2. Each $s \in S$ must be homogeneous of even degree.
3. We have $S \subseteq N(A)$.

Given a multiplicatively closed subset $S \subseteq A$, we define an MDG R -algebra A_S , called the **localization of A at S** , as follows: as a set, A_S is given by

$$A_S := \{a/s \mid a \in A \text{ and } s \in S\}$$

where a/s denotes the equivalence class of $(a, s) \in A \times S$ with respect to the following equivalence relation:

$$(a, s) \sim (a', s') \text{ if and only if there exists } s'' \in S \text{ such that } s''s'a = s''sa'. \quad (44)$$

Notice how we are not bothering to put in parenthesis in (44) since each $s \in S$ belongs to the nucleus of A and thus associates with everything else. One can check that (44) is indeed an equivalence relation because every $s \in S$ associates and commutes with everything else. We give A_S the structure of an R -module by defining addition and R -scalar multiplication on A_S by

$$\frac{a_1}{s_1} + \frac{a_2}{s_2} = \frac{s_2a_1 + s_1a_2}{s_1s_2} \quad \text{and} \quad r \cdot \frac{a}{s} = \frac{ra}{s}, \quad (45)$$

for all $a/s, a_1/s_1$, and a_2/s_2 in A_S , and for all $r \in R$. Again, (45) is well-defined since $S \subseteq N(A) \cap Z(A)$ where $Z(A)$ is the center of A (the set of all elements which commutes with everything else). In fact, A_S is a graded R -module where the homogeneous component in degree $i \in \mathbb{Z}$, denoted $A_{S,i}$, is the R -span of all fractions of the form a/s where a is homogeneous and where $|a/s| := i = |a| - |s|$. We give A_S the structure of an R -complex by attaching to it the differential $d_S: A_S \rightarrow A_S$ which is defined by

$$d_S \left(\frac{a}{s} \right) = \frac{d(a)s - (-1)^{|a|}ad(s)}{s^2}$$

for all $a/s \in A_S$. A straightforward computation shows that $d_S: A_S \rightarrow A_S$ is a graded R -linear map of degree -1 which satisfies $d_S^2 = 0$, so d_S really is a differential. As usual, we denote d_S more simply by d if context is understood. Finally we give A_S the structure of an MDG R -algebra by defining the multiplication μ_S of A_S via the formula

$$\frac{a_1}{s_1} \frac{a_2}{s_2} = \frac{a_1a_2}{s_1s_2}$$

for all a_1/s_1 and a_2/s_2 in A_S .

If X is an MDG A -module and $S \subseteq A$ is a multiplicatively closed set such that $S \subseteq N_A(X)$, then we can also define an MDG A_S -module X_S , called **localization of X with respect to S** . The construction of X_S is almost identical to the construction of A_S , however we really do need to have $S \subseteq N_A(X)$ (and not just $S \subseteq N(A)$) in order for this construction to be well-defined). In particular, we cannot view localization as a functor

$$-_S: \mathbf{MDGmod}_A \rightarrow \mathbf{MDGmod}_{A_S}.$$

However if we consider the subcategory \mathbf{MDGmod}_A^* of \mathbf{MDGmod}_A , where the objects of \mathbf{MDGmod}_A^* are the MDG A -modules X such that $N(A) \subseteq N_A(X)$, then we do obtain a functor

$$-_S: \mathbf{MDGmod}_A^* \rightarrow \mathbf{MDGmod}_{A_S}^*.$$

6.2 Tensor

We now discuss the tensor complex $X \otimes_A Y$. The underlying graded R -module of $X \otimes_A Y$ in degree i is the R -span of homogeneous elementary tensors $x \otimes y$ where $|x| + |y| = i$ subject to the relations

$$\begin{aligned} (x_1 + x_2) \otimes y &= x_1 \otimes y + x_2 \otimes y \\ x \otimes (y_1 + y_2) &= x \otimes y_1 + x \otimes y_2 \end{aligned}$$

for all $x_1, x_2, x \in X$ and $y_1, y_2, y \in Y$ as well as the relations

$$a(x \otimes y) = ax \otimes y = (-1)^{|a||x|}x \otimes ay \quad (46)$$

for all homogeneous $a \in A$, $x \in X$, and $y \in Y$. The differential of the tensor complex $X \otimes_A Y$ is defined on homogeneous elementary tensors $x \otimes y$ by

$$d(x \otimes y) = d(x) \otimes y + (-1)^{|x|}x \otimes d(y).$$

The tensor complex $X \otimes_A Y$ inherits the structure of an MDG A -module where the A -scalar multiplication is defined via (46), thus $X \otimes_A Y$ is in fact an MDG A -module. A calculation shows that

$$[a_1, a_2, x \otimes y] = [a_1, a_2, x] \otimes y = (-1)^{|a_1+a_2||x|}x \otimes [a_1, a_2, y]$$

for all homogeneous $a_1, a_2 \in A$ and for all homogeneous elementary tensors $x \otimes y \in X \otimes_A Y$. In particular, if either X or Y is associative, then $X \otimes_A Y$ is associative. Here's an important warning to keep in mind when dealing with tensor complexes however: the map $\varphi: A \otimes_A X \rightarrow X$ defined by $\varphi(a \otimes x) = ax$ is *not* well-defined if X is not associative. Indeed, suppose $[a_1, a_2, x] \neq 0$. Then

$$\begin{aligned} 0 &= \varphi(0) \\ &= \varphi(a_1 a_2 \otimes x - a_1 \otimes a_2 x) \\ &= [a_1, a_2, x] \\ &\neq 0 \end{aligned}$$

shows that φ is not well-defined. More generally, given an MDG A -ideal \mathfrak{a} , the map $A/\mathfrak{a} \otimes_A X \rightarrow X/\mathfrak{a}X$, defined on elementary tensors by $\bar{a} \otimes x \mapsto \overline{ax}$, is only well-defined if $[X] \subseteq \mathfrak{a}X$. Similarly, given a multiplicative subset $S \subseteq N(A) \cap N(X)$, the map $A_S \otimes_A X \rightarrow X_S$, defined on elementary tensors by $(a/1) \otimes x \mapsto ax/1$, is only well-defined if $[X]_S = 0$.

6.3 Hom

Next we discuss the hom complex $\text{Hom}_A^*(X, Y)$. The hom complex $\text{Hom}_A^*(X, Y)$ is the R -complex whose underlying graded module in degree $i \in \mathbb{Z}$ is

$$\text{Hom}_A^*(X, Y)_i := \{\varphi: X \rightarrow Y \mid \varphi \text{ is a graded } A\text{-module homomorphism of degree } i\}.$$

A graded A -module homomorphism of degree $i := |\varphi|$ is a graded linear map $\varphi: X \rightarrow Y$ of degree $|\varphi|$ which satisfies $\varphi(ax) = (-1)^{|a||\varphi|}a\varphi(x)$ for all homogeneous $a \in A$ and $x \in X$. The differential of $\text{Hom}_A^*(X, Y)$ is denoted d^* and is defined on homogeneous $\varphi \in \text{Hom}_A^*(X, Y)$ by

$$d^*(\varphi) = d\varphi - (-1)^{|\varphi|}\varphi d.$$

Note that $d^*(\varphi)$ really is a graded A -module homomorphism of degree $|\varphi| - 1$! Indeed, for all homogeneous $a \in A$ and $x \in X$, we have

$$\begin{aligned} d^*(\varphi)(ax) &= (d\varphi)(ax) - (-1)^{|\varphi|}(\varphi d)(ax) \\ &= (-1)^{|a||\varphi|}d(a\varphi(x)) - (-1)^{|\varphi|}\varphi(d(ax)) - (-1)^{|\varphi|+|a|}\varphi(ad(x)) \\ &= (-1)^{|a||\varphi|}d(a)\varphi(x) + (-1)^{|a||\varphi|+|a|}a(d\varphi(x)) - (-1)^{|\varphi|+|\varphi|(|a|+1)}d(a)\varphi(x) - (-1)^{|\varphi|+|a|+|a||\varphi|}a\varphi(d(x)) \\ &= (-1)^{|a|(|\varphi|+1)}a(d\varphi(x)) - (-1)^{|\varphi|+|a|(|\varphi|+1)}a\varphi(d(x)) + (-1)^{|a||\varphi|}d(a)\varphi(x) - (-1)^{|a||\varphi|}d(a)\varphi(x) \\ &= (-1)^{|a|(|\varphi|+1)}a(d\varphi(x)) - (-1)^{|\varphi|+|a|(|\varphi|+1)}a(\varphi d(x)) \\ &= (-1)^{|a|(|\varphi|+1)}a(d\varphi(x)) - (-1)^{|\varphi|}\varphi d(x) \\ &= (-1)^{|a|(|\varphi|-1)}ad^*(\varphi)(x). \end{aligned}$$

The hom complex $\text{Hom}_A^*(X, Y)$ doesn't necessarily inherit the structure of an MDG A -module where the A -scalar multiplication is defined by $\varphi \mapsto a\varphi$ where $a\varphi: X \rightarrow Y$ is defined by

$$(a\varphi)(x) = (-1)^{|a||\varphi|}\varphi(ax) = a\varphi(x)$$

for all $x \in X$. Indeed, given homogeneous $a_1, a_2 \in A$ we have

$$\begin{aligned} (a_1\varphi)(a_2x) &= a_1\varphi(a_2x) \\ &= (-1)^{|a_2||\varphi|}a_1(a_2\varphi(x)) \\ &= (-1)^{|a_2||\varphi|}(a_1a_2)\varphi(x) - (-1)^{|a_2||\varphi|}[a_1, a_2, \varphi(x)] \\ &= (-1)^{|a_2||\varphi|+|a_1||a_2|}(a_2a_1)\varphi(x) - (-1)^{|a_2||\varphi|}[a_1, a_2, \varphi(x)] \\ &= (-1)^{|a_2||\varphi|+|a_1||a_2|}a_2(a_1\varphi(x)) + (-1)^{|a_2||\varphi|+|a_1||a_2|}[a_2, a_1, \varphi(x)] - (-1)^{|a_2||\varphi|}[a_1, a_2, \varphi(x)] \end{aligned}$$

for all $x \in X$. If we knew that

$$[a_1, a_2, \varphi(x)] = (-1)^{|a_1||a_2|}[a_2, a_1, \varphi(x)], \quad (47)$$

then we could continue the calculation and conclude that $a_1\varphi$ is A -linear, however we need not have the identity (47) in general. However recall that the identity (47) holding for all $a_1, a_2 \in A$ is equivalent to the condition that $\varphi(x) \in M(Y)$. Therefore if we knew that φ landed in $M(Y)$, then $a_1\varphi$ would be A -linear.

Just as in the case of the tensor product where it need not be true that $A \otimes_A X \simeq X$, it need not be the case that $\text{Hom}_A^*(A, X) \simeq X$. In fact, we have

$$\text{Hom}_A^*(A, X) \simeq N(X).$$

Indeed, suppose $\varphi \in \text{Hom}_A^*(A, X)$ and suppose $\varphi(1) = x$. Thus by A -linearity of φ , we have $\varphi(a) = (-1)^{|a||\varphi|}ax$ for all $a \in A$. Note that

$$\begin{aligned} 0 &= \varphi([a_1, a_2, 1]) \\ &= [a_1, a_2, \varphi(1)] \\ &= [a_1, a_2, x] \end{aligned}$$

for all $a_1, a_2 \in A$ forces $x \in N(X)$.
