

Algebro-Geometric Classification

Let \mathbb{k} be a commutative ring and let F be a finite free graded \mathbb{k} -module such that $F_0 = \mathbb{k}$, $F_i = 0$ for all $i < 0$, and $F_+ \neq 0$. In this note, we give an algebro-geometric classification of various structures we can attach to F . We begin by classifying all \mathbb{k} -complex structures on F which fixed the identity element $1 \in \mathbb{k} = F_0$.

Classifying \mathbb{k} -Complex Structures on F

Let us state up front what we wish to prove:

Theorem 0.1. *We have the following bijection of sets:*

$$\left\{ \text{GL}_n(\mathbb{k})\text{-orbits of } h_{A_{\mathbb{k}}^d(F)}(\mathbb{k}) \right\} \longleftrightarrow \left\{ \begin{array}{l} \text{isomorphism classes of } \mathbb{k}\text{-complex} \\ \text{structures on } F \text{ with fixed identity} \end{array} \right\}$$

where $A_{\mathbb{k}}^d(F)$ is a \mathbb{k} -algebra (to be constructed below) and where

$$h_{A_{\mathbb{k}}^d(F)}(\mathbb{k}) := \text{Hom}_{\mathbb{k}\text{-alg}}(A_{\mathbb{k}}^d(F), \mathbb{k})$$

is the \mathbb{k} -valued points of $A_{\mathbb{k}}^d(F)$. Two \mathbb{k} -complex structures (F, d) and (F, d') on F are said to be isomorphic with fixed identity if there exists a chain map $\varphi: F \rightarrow F$ such that $\varphi(1) = 1$.

The proof of this theorem mostly involves setting up our notation which will be used later on when we wish to classify other algebraic structures on F .

Proof. Let d be a \mathbb{k} -linear differential on F , meaning $d: F \rightarrow F$ is a graded \mathbb{k} -linear map of degree -1 which satisfies $d^2 = 0$. Choose an ordered homogeneous basis $e = (e_0, e_1, \dots, e_n)$ of F where we set $e_0 = 1$ and let $d = (d_j^i)$ be the matrix representation of the differential d with respect to the ordered homogeneous basis e . Thus we have $de = ed$ where $de = (0, de_1, \dots, de_n)$ and ed is the product of the row vector e on the left with the matrix d on the right. Alternatively we could express this in terms of the matrix entries of d : for each $0 \leq j \leq n$ we have

$$de_j = \sum_{0 \leq i \leq n} d_j^i e_i.$$

Note that since d is graded of degree -1 , we necessarily have $d_j^i = 0$ whenever $|e_i| \neq |e_j| - 1$. Also note that since $d^2 = 0$, we have $d^2 = 0$. Again we can express this in terms of matrix entries of d : for each $0 \leq i, j \leq n$ we have

$$\sum_{0 \leq t \leq n} d_j^t d_t^i = 0 \tag{1}$$

Now consider the following polynomial ring following polynomial ring

$$\mathbb{k}[D] = \mathbb{k}[\{D_j^i \mid 0 \leq i, j \leq n\}]$$

where the D_j^i are coordinates which correspond to the matrix entries of d . Let $e_d: \mathbb{k}[D] \rightarrow \mathbb{k}$ be the \mathbb{k} -algebra homomorphism given by $e_d(D) = d$ and set $\mathfrak{q}_d = \langle D - d \rangle$ to be the kernel of this evaluation map: it is the $\mathbb{k}[D]$ -ideal generated by $D_j^i - d_j^i$ for all $0 \leq i, j \leq n$. Note that if \mathbb{k} is an integral domain, then \mathfrak{q}_d is a prime ideal since $\mathbb{k}[D]/\mathfrak{q}_d \cong \mathbb{k}$, and if \mathbb{k} is a field, then \mathfrak{q}_d is a maximal ideal of $\mathbb{k}[D]$ and $\mathbb{k} \rightarrow \mathbb{k}[D]/\mathfrak{q}_d$ is a finite extension of fields. For each $0 \leq i, j \leq n$ we define the quadratic polynomials $\Delta_j^i \in \mathbb{k}[D]$ by:

$$\Delta_j^i := \sum_{0 \leq t \leq n} D_j^t D_t^i.$$

Then we see that the evaluation map $e_d: \mathbb{k}[\mathbf{D}] \rightarrow R$ factors through a unique \mathbb{k} -algebra homomorphism $\bar{e}_d: A_{\mathbb{k}}^d(F) \rightarrow \mathbb{k}$ where we set

$$A_{\mathbb{k}}^d(F) := \mathbb{k}[\mathbf{D}] / \langle \Delta \rangle \cup \langle \{D_j^i \mid |e_i| \neq |e_j| - 1\} \rangle$$

where we set $\Delta = (\Delta_j^i)$. Conversely, suppose $e_r: \mathbb{k}[\mathbf{D}] \rightarrow \mathbb{k}$ is another \mathbb{k} -algebra homomorphism where $e_r(\mathbf{D}) = \mathbf{r}$ where $\mathbf{r} = (r_j^i)$. Then we define a differential d_r on F by $d_r e := e_r$. Thus if we set $\text{Diff}_{\mathbb{k}}(F)$ be the set of all \mathbb{k} -linear differentials on F , then we have a bijection of sets:

$$h_{A_{\mathbb{k}}^d(F)}(\mathbb{k}) := \text{Hom}_{\mathbb{k}\text{-alg}}(A_{\mathbb{k}}^d(F), \mathbb{k}) \simeq \text{Diff}_{\mathbb{k}}(F).$$

Now suppose that $e' = (1, e'_1, \dots, e'_n)$ is another ordered homogeneous basis of F . Thus there is a graded \mathbb{k} -linear isomorphism $\varphi: F \rightarrow F$ such that $\varphi e = e'$. Let $\tilde{\gamma}_\varphi = \begin{pmatrix} 1 & 0 \\ 0 & \gamma_\varphi \end{pmatrix}$ be the matrix representation of φ with respect to e where $\gamma_\varphi \in \text{GL}_n(\mathbb{k})$. Thus we have $\varphi e = e' = e \tilde{\gamma}_\varphi$. Then the matrix representation of d in the e' coordinates is given by $d' = \tilde{\gamma}_\varphi^{-1} d \tilde{\gamma}_\varphi$ since

$$\begin{aligned} d e' &= d e \tilde{\gamma}_\varphi \\ &= e d \tilde{\gamma}_\varphi \\ &= e' \tilde{\gamma}_\varphi^{-1} d \tilde{\gamma}_\varphi \\ &= e' d'. \end{aligned}$$

Thus we see that $\text{GL}_n(\mathbb{k})$ acts on $h_{A_{\mathbb{k}}^d(F)}(\mathbb{k})$ by conjugation $e_d \mapsto e_{\tilde{\gamma}_\varphi^{-1} d \tilde{\gamma}_\varphi}$. On the other hand, if we define $d': F \rightarrow F$ by $d' = \varphi^{-1} d \varphi$, then we obtain $d' e = e d'$, hence d' is the differential on F whose matrix representation with respect to our original ordered basis e is d' . In particular, e_d and $e_{d'}$ belong to the same $\text{GL}_n(\mathbb{k})$ -orbit in $h_{A_{\mathbb{k}}^d(F)}(\mathbb{k})$ if and only if the corresponding differentials d and d' give isomorphic \mathbb{k} -complex structures on F with fixed identity. \square

Base Change

Suppose that R is a \mathbb{k} -algebra. Then $G := F \otimes_{\mathbb{k}} R$ is a finite free graded R -module with $G_0 \simeq R$, $G_i = 0$ for all $i < 0$, and $G_+ \neq 0$. We set

$$A_R^d(G) := A_{\mathbb{k}}^d(F) \otimes_{\mathbb{k}} R \simeq R[\mathbf{D}] / \langle \Delta \rangle \cup \langle \{D_j^i \mid |e_i| \neq |e_j| - 1\} \rangle.$$

It is clear that we have an inclusion of sets $h_{A_{\mathbb{k}}^d(F)}(R) \subseteq h_{A_R^d(G)}(R)$.

Proposition 0.1. *Let $G = \text{Aut}(R/\mathbb{k})$. Then G acts on $h_{A_R^d(G)}(R)$ and the set of all fixed points is precisely $h_{A_{\mathbb{k}}^d(F)}(R)$.*

Classifying Other Algebraic Structures on F

Let $\lambda: F \rightarrow F$ and $\mu: F \otimes_R F \rightarrow F$ be graded R -linear maps. With F equipped with λ and μ as above, we make the following definitions:

1. We say F is **unital** if $\lambda(1) = 1$ and $\mu(1 \otimes a) = a = \mu(a \otimes 1)$ for all $a \in F$.
2. We say F is **graded-commutative** (or μ is **graded-commutative**) if

$$ab = (-1)^{|a||b|} ba$$

for all homogeneous $a, b \in F$. We say it is **strictly graded-commutative** if it is graded-commutative and satisfies the additional property that

$$a^2 = 0$$

for all homogeneous $a \in F$ whenever $|a|$ is odd.

3. We say F is **multiplicative** (or λ is **μ -multiplicative**) if it satisfies the **multiplicative law**:

$$\lambda(ab) = \lambda(a)\lambda(b)$$

for all $a, b \in F$

4. We say F is **hom-associative** (or μ is λ -**associative**) if it satisfies the **hom-associative law**:

$$(ab)\lambda(c) = \lambda(a)(bc)$$

for all $a, b, c \in F$.

5. We say F is **permutative** (or μ is λ -**permutative**) if it satisfies the **permutative law**:

$$(\lambda(a)\lambda(b))\lambda(cd) = \lambda(ab)(\lambda(c)\lambda(d)) \quad (2)$$

for all $a, b, c, d \in F$.

Why are we interested in these definitions? Basically we view permutativity as a mixture between hom-associativity and multiplicativity.

Proposition 0.2. *Let $F = (F, d, \lambda, \mu)$ be an MLDG algebra.*

1. *If F is multiplicative, then F is permutative. The converse is true if F is unital.*
2. *If F is hom-associative, then F is permutative. In particular, if F is unital, then hom-associativity implies multiplicativity.*

Proof. 1. It is clear that if F is multiplicative, then F is permutative. Now suppose that F is unital and permutative. Then setting $c = 1 = d$ in (2) shows that F is multiplicative. In the general case where λ is not necessarily unital, we have $\lambda(1) = e$ where $e \in F_0$. In this case, the permutative law would imply that e associates with all of the other elements, and furthermore it would tell us that $e\lambda(ab) = e^2\lambda(a)\lambda(b)$ for all $a, b \in A$ (which is not quite the same as F being multiplicative).

2. Suppose F is hom-associative. Then for all $a, b, c, d \in F$, we have

$$\begin{aligned} \lambda(ab)(\lambda(c)\lambda(d)) &= ((ab)\lambda(c))\lambda^2(d) \\ &= (\lambda(a)(bc))\lambda^2(d) \\ &= \lambda^2(a)((bc)\lambda(d)) \\ &= \lambda^2(a)(\lambda(b)(cd)) \\ &= (\lambda(a)\lambda(b))\lambda(cd). \end{aligned}$$

There's a cute way to visualize this by tracing the edges of the permutohedron (the hexagon) below:

Note that the red edge “collapses” to the associahedra (the pentagon) if $\lambda = 1$. \square

Example 0.1. Let $\lambda \in R$ and let A be an MLDG R -algebra with $\lambda_A = m_\lambda$ being the multiplication by λ map given by $a \mapsto \lambda a$. Recall that A is R -linear, so in particular the element λ must be associative with all pairs of elements of A . It follows that A is permutative since

$$\begin{aligned} \lambda(ab)(\lambda(c)\lambda(d)) &= \lambda^3((ab)(cd)) \\ &= (\lambda(a)\lambda(b))\lambda(cd). \end{aligned}$$

On the other hand, A is not necessarily hom-associative. Indeed, we have

$$\lambda(a)(bc) = (ab)\lambda(c) \iff \lambda(a(bc) - (ab)c)$$

for all $a, b, c \in A$ and the righthand side need not be zero. It is easy to see though that A is hom-associative if and only if λ kills $\text{im}[\cdot, \cdot, \cdot]$ where $[\cdot, \cdot, \cdot]$ is the usual associator map defined by $[a, b, c] = a(bc) - (ab)c$ for all $a, b, c \in A$. Similarly, A is not necessarily multiplicative. Indeed, we have

$$\begin{aligned} \lambda(ab) - \lambda(a)\lambda(b) &= \lambda(ab - \lambda ab) \\ &= \lambda(1 - \lambda)ab \end{aligned}$$

for all $a, b \in A$. If we assume that R is local and that $\lambda \in \mathfrak{m}$, then $1 - \lambda$ is a unit. Then in this case, it is easy to see that A is multiplicative if and only if λ kills $\text{im} \mu$.

We now repeat the same procedure that we did when classifying \mathbb{k} -complex structures on F . Let $\lambda = (\ell_j^i)$ and let $m = (m_{i,j}^k)$ be their matrix representations with respect to e respectively. Thus we have $\lambda e = e \lambda$ we have $\mu(e^\top \otimes e) = e^\top m e$. In terms of the matrix entries, these are given by

$$\lambda(e_j) = \sum_i \ell_j^i e_i \quad \text{and} \quad \mu(e_i \otimes e_j) = \sum_k m_{i,j}^k e_k.$$

for all i, j .

Let $\mathbb{k}[D, L, M] = \mathbb{k}[\{D_i^j, L_i^j, M_{i,j}^k\}]$. We express the algebraic laws introduced above in terms of coordinates in the table below:

Algebraic Law	Equation
Graded-Commutative Law	$\Gamma_{i,j}^k = M_{i,j}^k - (-1)^{ e_i e_j } M_{j,i}^k$
Leibniz Law	$\Lambda_{i,j}^k = \sum_l (M_{i,j}^l D_l^k - D_i^l M_{l,j}^k - (-1)^{ e_i e_j } D_j^l M_{i,l}^k)$
Multiplicative Law	$\Theta_{i,j}^k = \sum_l M_{i,j}^l L_l^k - \sum_{l_1, l_2} L_i^{l_1} L_j^{l_2} M_{l_1, l_2}^k$
Hom-Associative Law	$H_{i,j,k}^l = \sum_{l_1, l_2} (M_{i,j}^{l_1} L_k^{l_2} M_{l_1, l_2}^l - M_{j,k}^{l_1} L_i^{l_2} M_{l_2, l_1}^l)$
Permutative Law	$\Pi_{i,j,k,l}^m = \sum_{l_1, l_2, l_3, l_4, l_5} (M_{i,j}^{l_1} L_k^{l_2} L_l^{l_3} - M_{k,l}^{l_1} L_i^{l_2} L_j^{l_3}) M_{l_2, l_3}^{l_4} L_{l_1}^{l_5} M_{l_5, l_4}^k$

We define

$$\begin{aligned}
A_{\mathbb{k}}^p(F) &= \mathbb{k}[L, M] / \langle \Pi \rangle. \\
A_{\mathbb{k}}^{pd}(F) &= \mathbb{k}[D, L, M] / \langle \Delta, \Pi \rangle \\
A_{\mathbb{k}}^h(F) &= \mathbb{k}[L, M] / \langle H \rangle \\
A_{\mathbb{k}}^{\setminus}(F) &= \mathbb{k}[L, M] / \langle \Theta \rangle \\
A_{\mathbb{k}}^c(F) &= \mathbb{k}[M] / \langle \Gamma \rangle,
\end{aligned}$$

and so on.
